

# ADC12D2000RF

## 12-Bit, Single 4.0 GSPS RF Sampling ADC

### 1.0 General Description

The 12-bit 2.0 GSPS ADC12D2000RF is an RF-sampling GSPS ADC that can directly sample input frequencies up to and above 2.7 GHz. The ADC12D2000RF augments the very large Nyquist zone of Texas Instruments' GSPS ADCs with excellent noise and linearity performance at RF frequencies, extending its usable range beyond the 3<sup>rd</sup> Nyquist zone.

The ADC12D2000RF provides a flexible LVDS interface which has multiple SPI programmable options to facilitate board design and FPGA/ASIC data capture. The LVDS outputs are compatible with IEEE 1596.3-1996 and supports programmable common mode voltage. The product is packaged in a lead-free 292-ball thermally enhanced BGA package over the rated industrial temperature range of -40°C to +85°C.

**To achieve the full rated performance for Fclk > 1.6 GHz, it is necessary to write the max power settings once to Register 6h via the Serial Interface; see [Section 19.0 Register Definitions](#) for more information.**

### 2.0 Applications

- 3G/4G Wireless Basestation
  - Receive Path
  - DPD Path
- Wideband Microwave Backhaul
- RF Sampling Software Defined Radio
- Military Communications
- SIGINT
- RADAR / LIDAR
- Wideband Communications
- Consumer RF
- Test and Measurement

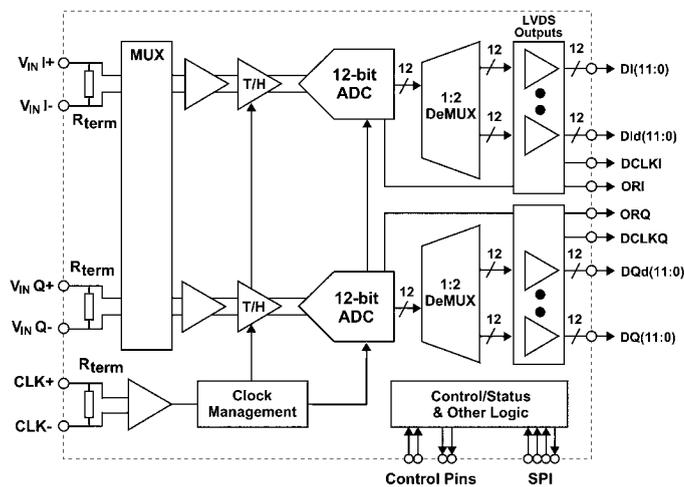

### 3.0 Features

- Excellent noise and linearity up to and above  $f_{IN} = 2.7$  GHz
- Configurable to either 4.0 GSPS interleaved or 2.0 GSPS dual ADC
- New DESCLKIQ Mode for high bandwidth, high sampling rate apps
- Pin-compatible with ADC1xD1x00, ADC12Dx00RF
- Internally terminated, buffered, differential analog inputs
- Interleaved timing automatic and manual skew adjust
- Test patterns at output for system debug
- Time Stamp feature to capture external trigger
- Programmable gain, offset, and  $t_{AD}$  adjust feature
- 1:1 non-demuxed or 1:2 demuxed LVDS outputs

### 4.0 Key Specifications

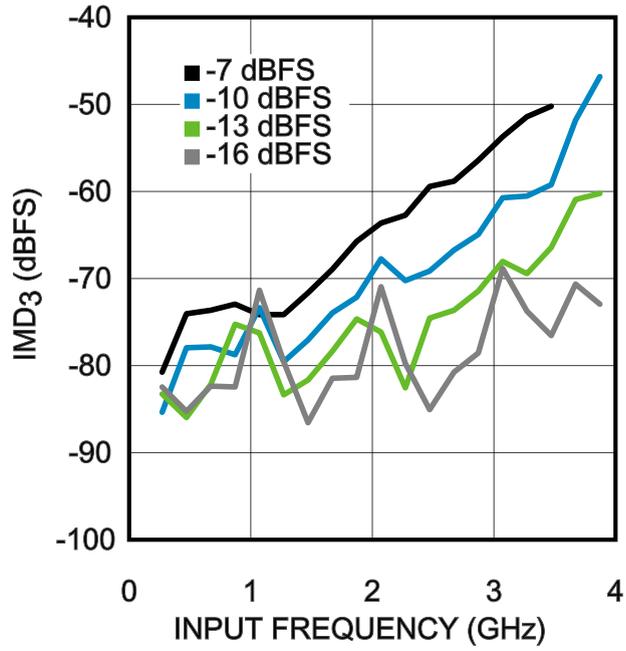

■ Resolution	12 Bits
Interleaved 4.0 GSPS ADC	
■ IMD <sub>3</sub> (Fin = 2.7GHz @ -13dBFS)	-60.6 dBc (typ)
■ IMD <sub>3</sub> (Fin = 2.7GHz @ -16dBFS)	-64.7 dBc (typ)
■ Noise Floor Density	-154 dBm/Hz (typ)
■ Power	4.6 W (typ)
Dual 2.0 GSPS ADC, Fin = 498 MHz	
■ ENOB	8.7 Bits (typ)
■ SNR	54.8 dB (typ)
■ SFDR	64.6 dBc (typ)
■ Power per Channel	2.3 W (typ)

## 9.0 Ball Descriptions and Equivalent Circuits

TABLE 1. Analog Front-End and Clock Balls

Ball No.	Name	Equivalent Circuit	Description
H1/J1 N1/M1	VinI+/- VinQ+/-		<p>Differential signal I- and Q-inputs. In the Non-Dual Edge Sampling (Non-DES) Mode, each I- and Q-input is sampled and converted by its respective channel with each positive transition of the CLK input. In Non-ECM (Non-Extended Control Mode) and DES Mode, both channels sample the I-input. In Extended Control Mode (ECM), the Q-input may optionally be selected for conversion in DES Mode by the DEQ Bit (Addr: 0h, Bit 6).</p> <p>Each I- and Q-channel input has an internal common mode bias that is disabled when DC-coupled Mode is selected. Both inputs must be either AC- or DC-coupled. The coupling mode is selected by the <math>V_{CMO}</math> Pin.</p> <p>In Non-ECM, the full-scale range of these inputs is determined by the FSR Pin; both I- and Q-channels have the same full-scale input range. In ECM, the full-scale input range of the I- and Q-channel inputs may be independently set via the Control Register (Addr: 3h and Addr: Bh).</p> <p>The input offset may also be adjusted in ECM.</p>
U2/V1	CLK+/-		<p>Differential Converter Sampling Clock. In the Non-DES Mode, the analog inputs are sampled on the positive transitions of this clock signal. In the DES Mode, the selected input is sampled on both transitions of this clock. This clock must be AC-coupled.</p>
V2/W1	DCLK_RST+/-		<p>Differential DCLK Reset. A positive pulse on this input is used to reset the DCLKI and DCLKQ outputs of two or more ADC12D2000RFs in order to synchronize them with other ADC12D2000RFs in the system. DCLKI and DCLKQ are always in phase with each other, unless one channel is powered down, and do not require a pulse from DCLK_RST to become synchronized. The pulse applied here must meet timing relationships with respect to the CLK input.</p>

Ball No.	Name	Equivalent Circuit	Description
C2	V <sub>CMO</sub>		<p>Common Mode Voltage Output or Signal Coupling Select. If AC-coupled operation at the analog inputs is desired, this pin should be held at logic-low level. This pin is capable of sourcing/sinking up to 100 <math>\mu</math>A. For DC-coupled operation, this pin should be left floating or terminated into high-impedance. In DC-coupled Mode, this pin provides an output voltage which is the optimal common-mode voltage for the input signal and should be used to set the common-mode voltage of the driving buffer.</p>
B1	V <sub>BG</sub>		<p>Bandgap Voltage Output or LVDS Common-mode Voltage Select. This pin provides a buffered version of the bandgap output voltage and is capable of sourcing / sinking 100 <math>\mu</math>A and driving a load of up to 80 pF. Alternately, this pin may be used to select the LVDS digital output common-mode voltage. If tied to logic-high, the 1.2V LVDS common-mode voltage is selected; 0.8V is the default.</p>
C3/D3	Rext+/-		<p>External Reference Resistor terminals. A 3.3 k<math>\Omega</math> <math>\pm</math>0.1% resistor should be connected between Rext+/- . The Rext resistor is used as a reference to trim internal circuits which affect the linearity of the converter; the value and precision of this resistor should not be compromised.</p>
C1/D2	Rtrim+/-		<p>Input Termination Trim Resistor terminals. A 3.3 k<math>\Omega</math> <math>\pm</math>0.1% resistor should be connected between Rtrim+/- . The Rtrim resistor is used to establish the calibrated 100<math>\Omega</math> input impedance of VinI, VinQ and CLK. These impedances may be fine tuned by varying the value of the resistor by a corresponding percentage; however, the tuning range and performance is not guaranteed for such an alternate value.</p>
E2/F3	Tdiode+/-		<p>Temperature Sensor Diode Positive (Anode) and Negative (Cathode) Terminals. This set of pins is used for die temperature measurements. It has not been fully characterized.</p>

Ball No.	Name	Equivalent Circuit	Description
Y4/W5	RCLK+/-		<p>Reference Clock Input.</p> <p><b>The AutoSync feature is not supported on the ADC12D2000RF.</b> The pin structures are still shown in the event that a design is supporting multiple pin compatible devices in the family that supports AutoSync, such as the ADC1xD1x00 and ADC12Dx00RF families. See <a href="#">Table 25</a> for recommendations about terminating unused pins.</p>
Y5/U6 V6/V7	RCOut1+/- RCOut2+/-		<p>Reference Clock Output 1 and 2.</p> <p><b>The AutoSync feature is not supported on the ADC12D2000RF.</b> The pin structures are still shown in the event that a design is supporting multiple pin compatible devices in the family that supports AutoSync, such as the ADC1xD1x00 and ADC12Dx00RF families. See <a href="#">Table 25</a> for recommendations about terminating unused pins.</p>

TABLE 2. Control and Status Balls

Ball No.	Name	Equivalent Circuit	Description
V5	DES		<p>Dual Edge Sampling (DES) Mode select. In the Non-Extended Control Mode (Non-ECM), when this input is set to logic-high, the DES Mode of operation is selected, meaning that the VinI input is sampled by both channels in a time-interleaved manner. The VinQ input is ignored. When this input is set to logic-low, the device is in Non-DES Mode, i.e. the I- and Q-channels operate independently. In the Extended Control Mode (ECM), this input is ignored and DES Mode selection is controlled through the Control Register by the DES Bit (Addr: 0h, Bit 7); default is Non-DES Mode operation.</p>
V4	CalDly		<p>Calibration Delay select. By setting this input logic-high or logic-low, the user can select the device to wait a longer or shorter amount of time, respectively, before the automatic power-on self-calibration is initiated. This feature is pin-controlled only and is always active during ECM and Non-ECM.</p>
D6	CAL		<p>Calibration cycle initiate. The user can command the device to execute a self-calibration cycle by holding this input high a minimum of <math>t_{CAL\_H}</math> after having held it low a minimum of <math>t_{CAL\_L}</math>. If this input is held high at the time of power-on, the automatic power-on calibration cycle is inhibited until this input is cycled low-then-high. This pin is active in both ECM and Non-ECM. In ECM, this pin is logically OR'd with the CAL Bit (Addr: 0h, Bit 15) in the Control Register. Therefore, both pin and bit must be set low and then either can be set high to execute an on-command calibration.</p>
B5	CalRun		<p>Calibration Running indication. This output is logic-high while the calibration sequence is executing. This output is logic-low otherwise.</p>

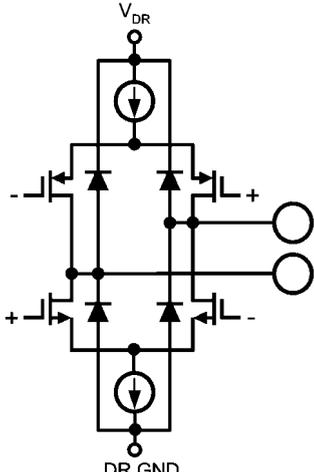

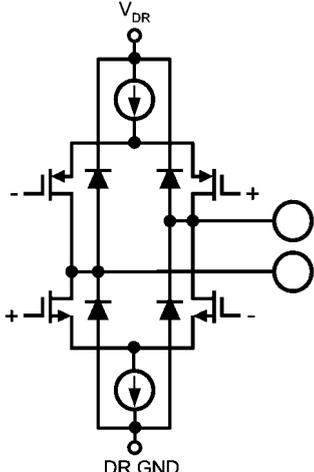

Ball No.	Name	Equivalent Circuit	Description
U3 V3	PDI PDQ		<p>Power Down I- and Q-channel. Setting either input to logic-high powers down the respective I- or Q-channel. Setting either input to logic-low brings the respective I- or Q-channel to an operational state after a finite time delay. This pin is active in both ECM and Non-ECM. In ECM, each Pin is logically OR'd with its respective Bit. Therefore, either this pin or the PDI and PDQ Bit in the Control Register can be used to power-down the I- and Q-channel (Addr: 0h, Bit 11 and Bit 10), respectively.</p>
A4	TPM		<p>Test Pattern Mode select. With this input at logic-high, the device continuously outputs a fixed, repetitive test pattern at the digital outputs. In the ECM, this input is ignored and the Test Pattern Mode can only be activated through the Control Register by the TPM Bit (Addr: 0h, Bit 12).</p>
A5	NDM		<p>Non-Demuxed Mode select. Setting this input to logic-high causes the digital output bus to be in the 1:1 Non-Demuxed Mode. Setting this input to logic-low causes the digital output bus to be in the 1:2 Demuxed Mode. This feature is pin-controlled only and remains active during ECM and Non-ECM.</p>
Y3	FSR		<p>Full-Scale input Range select. In Non-ECM, this input must be set to logic-high; the full-scale differential input range for both I- and Q-channel inputs is set by this pin. In the ECM, this input is ignored and the full-scale range of the I- and Q-channel inputs is independently determined by the setting of Addr: 3h and Addr: Bh, respectively. Note that the logic-high FSR value in Non-ECM corresponds to the minimum allowed selection in ECM.</p>
W4	DDRPh		<p>DDR Phase select. This input, when logic-low, selects the 0° Data-to-DCLK phase relationship. When logic-high, it selects the 90° Data-to-DCLK phase relationship, i.e. the DCLK transition indicates the middle of the valid data outputs. This pin only has an effect when the chip is in 1:2 Demuxed Mode, i.e. the NDM pin is set to logic-low. In ECM, this input is ignored and the DDR phase is selected through the Control Register by the DPS Bit (Addr: 0h, Bit 14); the default is 0° Mode.</p>

Ball No.	Name	Equivalent Circuit	Description
B3	$\overline{\text{ECE}}$		Extended Control Enable bar. Extended feature control through the SPI interface is enabled when this signal is asserted (logic-low). In this case, most of the direct control pins have no effect. When this signal is de-asserted (logic-high), the SPI interface is disabled, all SPI registers are reset to their default values, and all available settings are controlled via the control pins.
C4	$\overline{\text{SCS}}$		Serial Chip Select bar. In ECM, when this signal is asserted (logic-low), SCLK is used to clock in serial data which is present on SDI and to source serial data on SDO. When this signal is de-asserted (logic-high), SDI is ignored and SDO is in TRI-STATE.
C5	SCLK		Serial Clock. In ECM, serial data is shifted into and out of the device synchronously to this clock signal. This clock may be disabled and held logic-low, as long as timing specifications are not violated when the clock is enabled or disabled.
B4	SDI		Serial Data-In. In ECM, serial data is shifted into the device on this pin while $\overline{\text{SCS}}$ signal is asserted (logic-low).
A3	SDO		Serial Data-Out. In ECM, serial data is shifted out of the device on this pin while $\overline{\text{SCS}}$ signal is asserted (logic-low). This output is at TRI-STATE when $\overline{\text{SCS}}$ is de-asserted.
D1, D7, E3, F4, W3, U7	DNC	NONE	Do Not Connect. These pins are used for internal purposes and should not be connected, i.e. left floating. Do not ground.
C7	NC	NONE	Not Connected. This pin is not bonded and may be left floating or connected to any potential.

**TABLE 3. Power and Ground Balls**

Ball No.	Name	Equivalent Circuit	Description
A2, A6, B6, C6, D8, D9, E1, F1, H4, N4, R1, T1, U8, U9, W6, Y2, Y6	V <sub>A</sub>	NONE	Power Supply for the Analog circuitry. This supply is tied to the ESD ring. Therefore, it must be powered up before or with any other supply.
G1, G3, G4, H2, J3, K3, L3, M3, N2, P1, P3, P4, R3, R4	V <sub>TC</sub>	NONE	Power Supply for the Track-and-Hold and Clock circuitry.
A11, A15, C18, D11, D15, D17, J17, J20, R17, R20, T17, U11, U15, U16, Y11, Y15	V <sub>DR</sub>	NONE	Power Supply for the Output Drivers.
A8, B9, C8, V8, W9, Y8	V <sub>E</sub>	NONE	Power Supply for the Digital Encoder.
J4, K2	V <sub>biasI</sub>	NONE	Bias Voltage I-channel. This is an externally decoupled bias voltage for the I-channel. Each pin should individually be decoupled with a 100 nF capacitor via a low resistance, low inductance path to GND.
L2, M4	V <sub>biasQ</sub>	NONE	Bias Voltage Q-channel. This is an externally decoupled bias voltage for the Q-channel. Each pin should individually be decoupled with a 100 nF capacitor via a low resistance, low inductance path to GND.
A1, A7, B2, B7, D4, D5, E4, K1, L1, T4, U4, U5, W2, W7, Y1, Y7, H8:N13	GND	NONE	Ground Return for the Analog circuitry.
F2, G2, H3, J2, K4, L4, M2, N3, P2, R2, T2, T3, U1	GND <sub>TC</sub>	NONE	Ground Return for the Track-and-Hold and Clock circuitry.
A13, A17, A20, D13, D16, E17, F17, F20, M17, M20, U13, U17, V18, Y13, Y17, Y20	GND <sub>DR</sub>	NONE	Ground Return for the Output Drivers.
A9, B8, C9, V9, W8, Y9	GND <sub>E</sub>	NONE	Ground Return for the Digital Encoder.

TABLE 4. High-Speed Digital Outputs

Ball No.	Name	Equivalent Circuit	Description
<p>K19/K20 L19/L20</p>	<p>DCLKI+/- DCLKQ+/-</p>		<p>Data Clock Output for the I- and Q-channel data bus. These differential clock outputs are used to latch the output data and, if used, should always be terminated with a 100Ω differential resistor placed as closely as possible to the differential receiver. Delayed and non-delayed data outputs are supplied synchronously to this signal. In 1:2 Demux Mode or Non-Demux Mode, this signal is at ¼ or ½ the sampling clock rate, respectively. DCLKI and DCLKQ are always in phase with each other, unless one channel is powered down, and do not require a pulse from DCLK_RST to become synchronized.</p>
<p>K17/K18 L17/L18</p>	<p>ORI+/- ORQ+/-</p>		<p>Out-of-Range Output for the I- and Q-channel. This differential output is asserted logic-high while the over- or under-range condition exists, i.e. the differential signal at each respective analog input exceeds the full-scale value. Each OR result refers to the current Data, with which it is clocked out. If used, each of these outputs should always be terminated with a 100Ω differential resistor placed as closely as possible to the differential receiver. ORQ (<a href="#">Note 19</a>).</p>

Ball No.	Name	Equivalent Circuit	Description
J18/J19 H19/H20 H17/H18 G19/G20 G17/G18 F18/F19 E19/E20 D19/D20 D18/E18 C19/C20 B19/B20 B18/C17  M18/M19 N19/N20 N17/N18 P19/P20 P17/P18 R18/R19 T19/T20 U19/U20 U18/T18 V19/V20 W19/W20 W18/V17	DI11+/- DI10+/- DI9+/- DI8+/- DI7+/- DI6+/- DI5+/- DI4+/- DI3+/- DI2+/- DI1+/- DI0+/-  DQ11+/- DQ10+/- DQ9+/- DQ8+/- DQ7+/- DQ6+/- DQ5+/- DQ4+/- DQ3+/- DQ2+/- DQ1+/- DQ0+/-		<p>I- and Q-channel Digital Data Outputs. In Non-Demux Mode, this LVDS data is transmitted at the sampling clock rate. In Demux Mode, these outputs provide ½ the data at ½ the sampling clock rate, synchronized with the delayed data, i.e. the other ½ of the data which was sampled one clock cycle earlier. Compared with the DI<sub>d</sub> and DQ<sub>d</sub> outputs, these outputs represent the later time samples. If used, each of these outputs should always be terminated with a 100Ω differential resistor placed as closely as possible to the differential receiver.</p>

In Non-Demux Mode, these outputs are at TRI-STATE. In Demux Mode, these outputs provide ½ the data at ½ the sampling clock rate, synchronized with the non-delayed data, i.e. the other ½ of the data which was sampled one clock cycle later. Compared with the DI and DQ outputs, these outputs represent the earlier time samples. If used, each of these outputs should always be terminated with a 100Ω differential resistor placed as closely as possible to the differential receiver.</p>

## 10.0 Absolute Maximum Ratings

(Note 1, Note 2)

Supply Voltage ( $V_A, V_{TC}, V_{DR}, V_E$ )	2.2V
Supply Difference $\max(V_{A/TC/DR/E}) - \min(V_{A/TC/DR/E})$	0V to 100 mV
Voltage on Any Input Pin (except $V_{IN+/-}$ )	-0.15V to ( $V_A + 0.15V$ )
$V_{IN+/-}$ Voltage Range	-0.5V to 2.5V
Ground Difference $\max(GND_{TC/DR/E}) - \min(GND_{TC/DR/E})$	0V to 100 mV
Input Current at Any Pin (Note 3)	$\pm 50$ mA
ADC12D2000RF Package Power Dissipation at $T_A \leq 45^\circ\text{C}$ (Note 3)	5.34 W
ESD Susceptibility (Note 4)	
Human Body Model	2500V
Charged Device Model	1000V
Machine Model	250V
Storage Temperature	$-65^\circ\text{C}$ to $+150^\circ\text{C}$

## 11.0 Operating Ratings

(Note 1, Note 2)

Ambient Temperature Range	
ADC12D2000RF (Standard JEDEC thermal model)	$-40^\circ\text{C} \leq T_A \leq +45^\circ\text{C}$
ADC12D2000RF (Enhanced thermal model / heatsink)	$-40^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$
Junction Temperature Range - applies only to maximum operating speed	$T_J \leq +120^\circ\text{C}$
Supply Voltage ( $V_A, V_{TC}, V_E$ )	+1.9V to +2.1V
Driver Supply Voltage ( $V_{DR}$ )	+1.9V to $V_A$
$V_{IN+/-}$ Voltage Range (Note 14)	-0.4V to 2.4V (d.c.-coupled)
$V_{IN+/-}$ Differential Voltage Range (Note 15)	1.0V (d.c.-coupled @100% duty cycle) 2.0V (d.c.-coupled @20% duty cycle) 2.8V (d.c.-coupled @10% duty cycle)
$V_{IN+/-}$ Current Range (Note 14)	$\pm 50$ mA peak (a.c.-coupled)
$V_{IN+/-}$ Power	15.3 dBm (maintaining common mode voltage, a.c.-coupled) 17.1 dBm (not maintaining common mode voltage, a.c.-coupled)
Ground Difference $\max(GND_{TC/DR/E}) - \min(GND_{TC/DR/E})$	0V
CLK+/- Voltage Range	0V to $V_A$
Differential CLK Amplitude	$0.4V_{P-P}$ to $2.0V_{P-P}$
Common Mode Input Voltage	$V_{CMO} - 150\text{mV} < V_{CMI} < V_{CMO} + 150\text{mV}$

**TABLE 5. Package Thermal Resistance**

Package	$\theta_{JA}$	$\theta_{JC1}$	$\theta_{JC2}$
292-Ball BGA Thermally Enhanced Package	16°C/W	2.9°C/W	2.5°C/W

Soldering process must comply with Texas Instruments' Reflow Temperature Profile specifications. Refer to [www.national.com/packaging](http://www.national.com/packaging).

## 12.0 Converter Electrical Characteristics

Unless otherwise specified, the following apply after calibration for  $V_A = V_{DR} = V_{TC} = V_E = +2.0V$ ; I- and Q-channels, AC-coupled, unused channel terminated to AC ground, FSR Pin = High; Differential, AC coupled Sine Wave Sampling Clock,  $f_{CLK} = 2.0$  GHz at  $0.5 V_{P-P}$  with 50% duty cycle (as specified);  $V_{BG} =$  Floating; Extended Control Mode with Register 6h written to 1C0Eh; Rext = Rtrim =  $3300\Omega \pm 0.1\%$ ; Analog Signal Source Impedance =  $100\Omega$  Differential; 1:2 Demultiplex Non-DES Mode; Duty Cycle Stabilizer on. **Boldface limits apply for  $T_A = T_{MIN}$  to  $T_{MAX}$  and for  $T_J < 120^\circ C$ .** All other limits  $T_A = 25^\circ C$ , unless otherwise noted. ([Note 5](#), [Note 6](#), [Note 7](#))

### TABLE 6. Static Converter Characteristics

Symbol	Parameter	Conditions	ADC12D2000RF		Units (Limits)
			Typ	Lim	
	Resolution with No Missing Codes			<b>12</b>	bits
INL	Integral Non-Linearity (Best fit)	1 MHz DC-coupled over-ranged sine wave	$\pm 2.5$		LSB
DNL	Differential Non-Linearity	1 MHz DC-coupled over-ranged sine wave	$\pm 0.5$		LSB
$V_{OFF}$	Offset Error		5		LSB
$V_{OFF\_ADJ}$	Input Offset Adjustment Range	Extended Control Mode	$\pm 45$		mV
PFSE	Positive Full-Scale Error	( <a href="#">Note 8</a> )		<b><math>\pm 25</math></b>	mV (max)
NFSE	Negative Full-Scale Error	( <a href="#">Note 8</a> )		<b><math>\pm 25</math></b>	mV (max)
	Out-of-Range Output Code ( <a href="#">Note 9</a> )	$(V_{IN+}) - (V_{IN-}) > +$ Full Scale		<b>4095</b>	
		$(V_{IN+}) - (V_{IN-}) < -$ Full Scale		<b>0</b>

		CalDly = High		2 <sup>30</sup>	

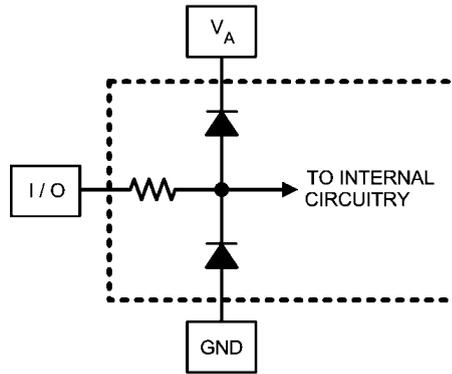

**Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. There is no guarantee of operation at the Absolute Maximum Ratings. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics. The guaranteed specifications apply only for the test conditions listed. Some performance characteristics may degrade when the device is not operated under the listed test conditions.

**Note 2:** All voltages are measured with respect to GND = GND<sub>TC</sub> = GND<sub>DR</sub> = GND<sub>E</sub> = 0V, unless otherwise specified.

**Note 3:** When the input voltage at any pin exceeds the power supply limits, i.e. less than GND or greater than V<sub>A</sub>, the current at that pin should be limited to 50 mA. In addition, over-voltage at a pin must adhere to the maximum voltage limits. Simultaneous over-voltage at multiple pins requires adherence to the maximum package power dissipation limits. These dissipation limits are calculated using JEDEC JESD51-7 thermal model. Higher dissipation may be possible based on specific customer thermal situation and specified package thermal resistances from junction to case.

**Note 4:** Human body model is 100 pF capacitor discharged through a 1.5 kΩ resistor. Machine model is 220 pF discharged through 0Ω. Charged device model simulates a pin slowly acquiring charge (such as from a device sliding down the feeder in an automated assembler) then rapidly being discharged.

**Note 5:** The analog inputs, labeled "I/O", are protected as shown below. Input voltage magnitudes beyond the Absolute Maximum Ratings may damage this device.

30173704

**Note 6:** To guarantee accuracy, it is required that  $V_A$ ,  $V_{TC}$ ,  $V_E$  and  $V_{DR}$  be well-bypassed. Each supply pin must be decoupled with separate bypass capacitors.

**Note 7:** Typical figures are at  $T_A = 25^\circ\text{C}$ , and represent most likely parametric norms. Test limits are guaranteed to Texas Instruments' AOQL (Average Outgoing Quality Level).

**Note 8:** Calculation of Full-Scale Error for this device assumes that the actual reference voltage is exactly its nominal value. Full-Scale Error for this device, therefore, is a combination of Full-Scale Error and Reference Voltage Error. See [Figure 3](#). For relationship between Gain Error and Full-Scale Error, see Specification Definitions for Gain Error.

**Note 9:** This parameter is guaranteed by design and is not tested in production.

**Note 10:** This parameter is guaranteed by design and/or characterization and is not tested in production.

**Note 11:** The Dynamic Specifications are guaranteed for room to hot ambient temperature only ( $25^\circ\text{C}$  to  $85^\circ\text{C}$ ). Refer to the plots of the dynamic performance vs. temperature in the Typical Performance Plots to see typical performance from cold to room temperature ( $-40^\circ\text{C}$  to  $25^\circ\text{C}$ ).

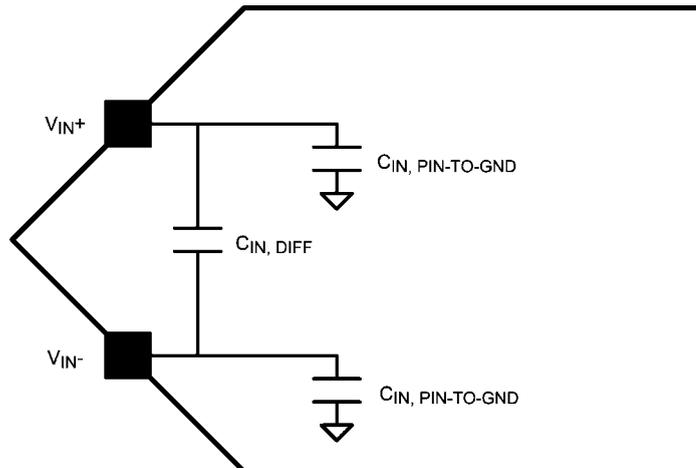

**Note 12:** These measurements were taken in Extended Control Mode (ECM) with the DES Timing Adjust feature enabled (Addr: 7h). This feature is used to reduce the interleaving timing spur amplitude, which occurs at  $f_s/2$ -fin, and thereby increase the SFDR, SINAD and ENOB.

**Note 13:** The  $F_s/2$  spur was removed from all the dynamic performance specifications.

**Note 14:** Proper common mode voltage must be maintained to ensure proper output codes, especially during input overdrive.

**Note 15:** This rating is intended for d.c.-coupled applications; the voltages listed may be safely applied to  $V_{IN+/-}$  for the life-time duty-cycle of the part.

**Note 16:** The differential and pin-to-ground input capacitances are lumped capacitance values from design; they are defined as shown below.

30173795

**Note 17:** The -3 dB point is the traditional Full-Power Bandwidth (FPBW) specification. Although the insertion loss is approximately half the power at this frequency, the dynamic performance of the ADC does not necessarily begin to degrade to a level below which it may be effectively used in an application. The ADC may be used at input frequencies above the -3 dB FPBW point, for example, into the 3rd Nyquist zone. Depending on system requirements, it is only necessary to compensate for the insertion loss.

**Note 18:** This feature functionality is not tested in production test; performance is tested in the specified / default mode only.

**Note 19:** This pin / bit functionality is not tested in production test; performance is tested in the specified / default mode only.

**Note 20:** Typical dynamic performance is only tested at  $f_{in} = 498$  MHz; other input frequencies are guaranteed by design and / or characterization and are not tested in production.

## 13.0 Specification Definitions

**APERTURE (SAMPLING) DELAY** is the amount of delay, measured from the sampling edge of the CLK input, after which the signal present at the input pin is sampled inside the device.

**APERTURE JITTER ( $t_{AJ}$ )** is the variation in aperture delay from sample-to-sample. Aperture jitter can be effectively considered as noise at the input.

**CODE ERROR RATE (CER)** is the probability of error and is defined as the probable number of word errors on the ADC output per unit of time divided by the number of words seen in that amount of time. A CER of  $10^{-18}$  corresponds to a statistical error in one word about every 31.7 years.

**CLOCK DUTY CYCLE** is the ratio of the time that the clock waveform is at a logic high to the total time of one clock period.

**DIFFERENTIAL NON-LINEARITY (DNL)** is the measure of the maximum deviation from the ideal step size of 1 LSB. It is measured at the relevant sample rate,  $f_{CLK}$ , with  $f_{IN} = 1\text{MHz}$  sine wave.

**EFFECTIVE NUMBER OF BITS (ENOB, or EFFECTIVE BITS)** is another method of specifying Signal-to-Noise and Distortion Ratio, or SINAD. ENOB is defined as  $(\text{SINAD} - 1.76) / 6.02$  and states that the converter is equivalent to a perfect ADC of this many (ENOB) number of bits.

**GAIN ERROR** is the deviation from the ideal slope of the transfer function. It can be calculated from Offset and Full-Scale Errors. The Positive Gain Error is the Offset Error minus the Positive Full-Scale Error. The Negative Gain Error is the Negative Full-Scale Error minus the Offset Error. The Gain Error is the Negative Full-Scale Error minus the Positive Full-Scale Error; it is also equal to the Positive Gain Error plus the Negative Gain Error.

**GAIN FLATNESS** is the measure of the variation in gain over the specified bandwidth. For example, for the ADC12D2000RF, from D.C. to  $F_s/2$  is to 1.0 GHz for the Non-DES Mode and from D.C. to  $F_s/2$  is 2.0 GHz for the DES Mode.

**INTEGRAL NON-LINEARITY (INL)** is a measure of worst case deviation of the ADC transfer function from an ideal straight line drawn through the ADC transfer function. The deviation of any given code from this straight line is measured from the center of that code value step. The best fit method is used.

**INSERTION LOSS** is the loss in power of a signal due to the insertion of a device, e.g. the ADC12D2000RF, expressed in dB.

**INTERMODULATION DISTORTION (IMD)** is a measure of the near-in 3rd order distortion products ( $2f_2 - f_1$ ,  $2f_1 - f_2$ ) which occur when two tones which are close in frequency ( $f_1$ ,  $f_2$ ) are applied to the ADC input. It is measured from the input tones level to the higher of the two distortion products (dBc) or simply the level of the higher of the two distortion products (dBFS). The input tones are typically -7dBFS.

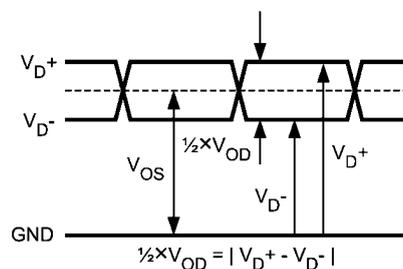

**LSB (LEAST SIGNIFICANT BIT)** is the bit that has the smallest value or weight of all bits. This value is

$$V_{FS} / 2^N$$

where  $V_{FS}$  is the differential full-scale amplitude  $V_{IN\_FSR}$  as set by the FSR input and "N" is the ADC resolution in bits, which is 12 for the ADC12D2000RF.

**LOW VOLTAGE DIFFERENTIAL SIGNALING (LVDS) DIFFERENTIAL OUTPUT VOLTAGE ( $V_{ID}$  and  $V_{OD}$ )** is two times the absolute value of the difference between the  $V_{D+}$  and  $V_{D-}$  signals; each signal measured with respect to

Ground.  $V_{OD}$  peak is  $V_{OD,P} = (V_{D+} - V_{D-})$  and  $V_{OD}$  peak-to-peak is  $V_{OD,P-P} = 2 * (V_{D+} - V_{D-})$ ; for this product, the  $V_{OD}$  is measured peak-to-peak.

30173746

FIGURE 2. LVDS Output Signal Levels

**LVDS OUTPUT OFFSET VOLTAGE ( $V_{OS}$ )** is the midpoint between the D+ and D- pins output voltage with respect to ground; i.e.,  $[(V_{D+}) + (V_{D-})]/2$ . See [Figure 2](#).

**MISSING CODES** are those output codes that are skipped and will never appear at the ADC outputs. These codes cannot be reached with any input value.

**MSB (MOST SIGNIFICANT BIT)** is the bit that has the largest value or weight. Its value is one half of full scale.

**NEGATIVE FULL-SCALE ERROR (NFSE)** is a measure of how far the first code transition is from the ideal 1/2 LSB above a differential  $-V_{IN}/2$ . For the ADC12D2000RF the reference voltage is assumed to be ideal, so this error is a combination of full-scale error and reference voltage error.

**NOISE FLOOR DENSITY** is a measure of the power density of the noise floor, expressed in dBFS/Hz and dBm/Hz. '0 dBFS' is defined as the power of a sinusoid which precisely uses the full-scale range of the ADC.

**NOISE POWER RATIO (NPR)** is the ratio of the sum of the power outside the notched bins to the sum of the power in an equal number of bins inside the notch, expressed in dB.

**OFFSET ERROR ( $V_{OFF}$ )** is a measure of how far the mid-scale point is from the ideal zero voltage differential input.

Offset Error = Actual Input causing average of 8k samples to result in an average code of 2047.5.

**OUTPUT DELAY ( $t_{OD}$ )** is the time delay (in addition to Latency) after the rising edge of CLK+ before the data update is present at the output pins.

**OVER-RANGE RECOVERY TIME** is the time required after the differential input voltages goes from  $\pm 1.2\text{V}$  to  $0\text{V}$  for the converter to recover and make a conversion with its rated accuracy.

**PIPELINE DELAY (LATENCY)** is the number of input clock cycles between initiation of conversion and when that data is presented to the output driver stage. The data lags the conversion by the Latency plus the  $t_{OD}$ .

**POSITIVE FULL-SCALE ERROR (PFSE)** is a measure of how far the last code transition is from the ideal 1-1/2 LSB below a differential  $+V_{IN}/2$ . For the ADC12D2000RF the reference voltage is assumed to be ideal, so this error is a combination of full-scale error and reference voltage error.

**SIGNAL TO NOISE RATIO (SNR)** is the ratio, expressed in dB, of the rms value of the fundamental for a single-tone to the rms value of the sum of all other spectral components below one-half the sampling frequency, not including harmonics or DC.

**SIGNAL TO NOISE PLUS DISTORTION (S/(N+D) or SINAD)** is the ratio, expressed in dB, of the rms value of the fundamental for a single-tone to the rms value of all of the other spectral components below half the input clock frequency, including harmonics but excluding DC.

**SPURIOUS-FREE DYNAMIC RANGE (SFDR)** is the difference, expressed in dB, between the rms values of the input signal at the output and the peak spurious signal, where a spurious signal is any signal present in the output spectrum that is not present at the input, excluding DC.

$\theta_{JA}$  is the thermal resistance between the junction to ambient.

$\theta_{JC1}$  represents the thermal resistance between the die and the exposed metal area on the top of the HSBGA package.

$\theta_{JC2}$  represents the thermal resistance between the die and the center group of balls on the bottom of the HSBGA package.

**TOTAL HARMONIC DISTORTION (THD)** is the ratio expressed in dB, of the rms total of the first nine harmonic levels at the output to the level of the fundamental at the output. THD is calculated as

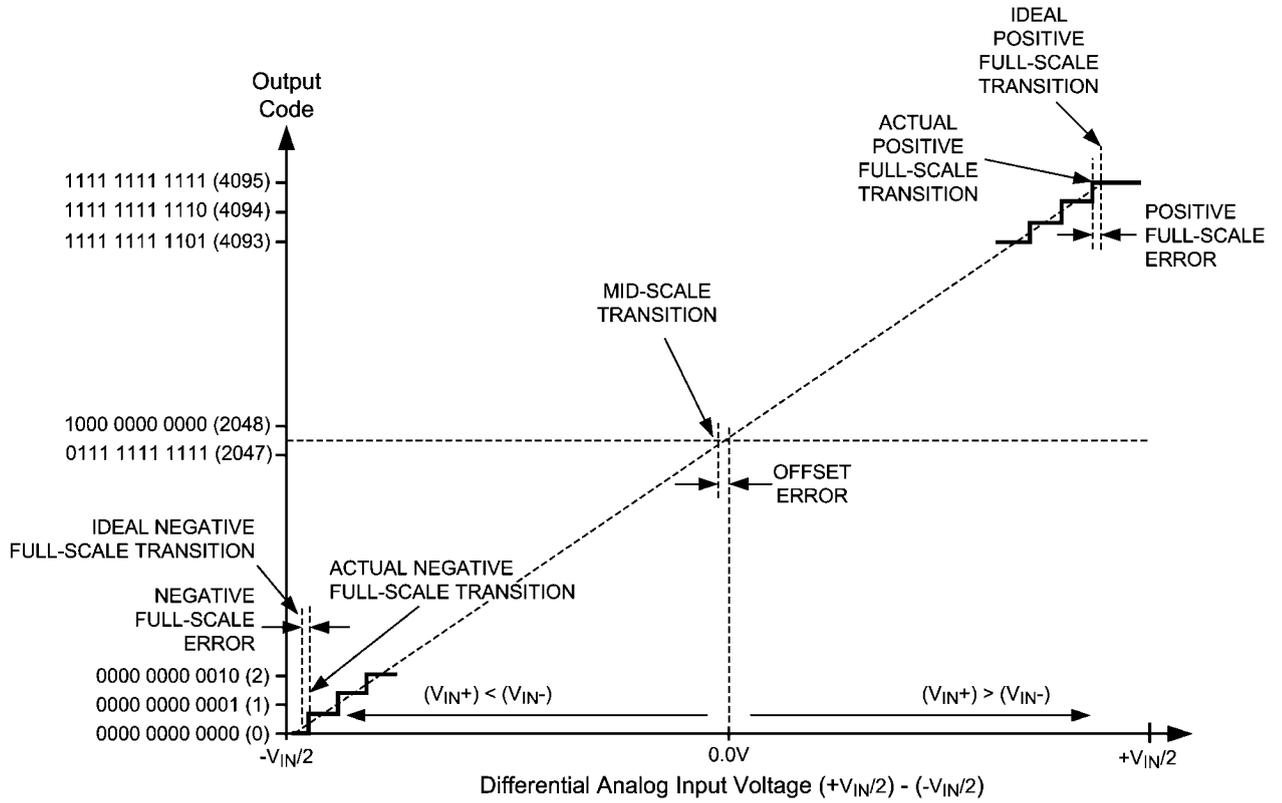

$$\text{THD} = 20 \times \log \sqrt{\frac{A_{f2}^2 + \dots + A_{f10}^2}{A_{f1}^2}}$$

where  $A_{f1}$  is the RMS power of the fundamental (output) frequency and  $A_{f2}$  through  $A_{f10}$  are the RMS power of the first 9 harmonic frequencies in the output spectrum.

– **Second Harmonic Distortion (2nd Harm)** is the difference, expressed in dB, between the RMS power in the input frequency seen at the output and the power in its 2nd harmonic level at the output.

– **Third Harmonic Distortion (3rd Harm)** is the difference expressed in dB between the RMS power in the input frequency seen at the output and the power in its 3rd harmonic level at the output.

## 17.0 Functional Description

The ADC12D2000RF is a versatile A/D converter with an innovative architecture which permits very high speed operation. The controls available ease the application of the device to circuit solutions. Optimum performance requires adherence to the provisions discussed here and in the Applications Information Section. This section covers an overview, a description of control modes (Extended Control Mode and Non-Extended Control Mode), and features.

### 17.1 OVERVIEW

The ADC12D2000RF uses a calibrated folding and interpolating architecture that achieves a high Effective Number of Bits (ENOB). The use of folding amplifiers greatly reduces the number of comparators and power consumption. Interpolation reduces the number of front-end amplifiers required, minimizing the load on the input signal and further reducing power requirements. In addition to correcting other non-idealities, on-chip calibration reduces the INL bow often seen with folding architectures. The result is an extremely fast, high performance, low power converter.

The analog input signal (which is within the converter's input voltage range) is digitized to twelve bits at speeds of 200 MSPS to 4.0 GSPS, typical. Differential input voltages below negative full-scale will cause the output word to consist of all zeroes. Differential input voltages above positive full-scale will cause the output word to consist of all ones. Either of these conditions at the I- or Q-input will cause the Out-of-Range I-channel or Q-channel output (ORI or ORQ), respectively, to output a logic-high signal.

In ECM, an expanded feature set is available via the Serial Interface. The ADC12D2000RF builds upon previous architectures, introducing a new DES Mode Timing Adjust, and increasing to 15-bit for gain and 12-bit plus sign for offset the independent programmable adjustment for each channel.

Each channel has a selectable output demultiplexer which feeds two LVDS buses. If the 1:2 Demux Mode is selected, the output data rate is reduced to half the input sample rate on each bus. When Non-Demux Mode is selected, the output data rate on each channel is at the same rate as the input sample clock and only one 12-bit bus per channel is active.

### 17.2 CONTROL MODES

The ADC12D2000RF may be operated in one of two control modes: Non-extended Control Mode (Non-ECM) or Extended Control Mode (ECM). In the simpler Non-ECM (also sometimes referred to as Pin Control Mode), the user affects available configuration and control of the device through the control pins. The ECM provides additional configuration and control options through a serial interface and a set of 16 registers, most of which are available to the customer.

#### 17.2.1 Non-Extended Control Mode

In Non-extended Control Mode (Non-ECM), the Serial Interface is not active and all available functions are controlled via various pin settings. Non-ECM is selected by setting the  $\overline{\text{ECE}}$  Pin to logic-high. Note that, for the control pins, "logic-high" and "logic-low" refer to  $V_A$  and GND, respectively. Nine dedicated control pins provide a wide range of control for the ADC12D2000RF and facilitate its operation. These control pins provide DES Mode selection, Demux Mode selection, DDR Phase selection, execute Calibration, Calibration Delay setting, Power Down I-channel, Power Down Q-channel, Test Pattern Mode selection, and Full-Scale Input Range selection. In addition to this, two dual-purpose control pins provide

for AC/DC-coupled Mode selection and LVDS output common-mode voltage selection. See [Table 16](#) for a summary.

TABLE 16. Non-ECM Pin Summary

Pin Name	Logic-Low	Logic-High	Floating
<b>Dedicated Control Pins</b>			
DES	Non-DES Mode	DES Mode	Not valid
NDM	Demux Mode	Non-Demux Mode	Not valid
DDRPh	0° Mode	90° Mode	Not valid
CAL	See <a href="#">Section 17.2.1.4 Calibration Pin (CAL)</a>		Not valid
CalDly	Shorter delay	Longer delay	Not valid
PDI	I-channel active	Power Down I-channel	Power Down I-channel
PDQ	Q-channel active	Power Down Q-channel	Power Down Q-channel
TPM	Non-Test Pattern Mode	Test Pattern Mode	Not valid
FSR	Not allowed	Nominal FS input Range	Not valid
<b>Dual-purpose Control Pins</b>			
$V_{\text{CMO}}$	AC-coupled operation	Not allowed	DC-coupled operation
$V_{\text{BG}}$	Not allowed	Higher LVDS common-mode voltage	Lower LVDS common-mode voltage

#### 17.2.1.1 Dual Edge Sampling Pin (DES)

The Dual Edge Sampling (DES) Pin selects whether the ADC12D2000RF is in DES Mode (logic-high) or Non-DES Mode (logic-low). DES Mode means that a single analog input is sampled by both I- and Q-channels in a time-interleaved manner. One of the ADCs samples the input signal on the rising sampling clock edge (duty cycle corrected); the other ADC samples the input signal on the falling sampling clock edge (duty cycle corrected). In Non-ECM, only the I-input may be used for DES Mode, a.k.a. "DESI Mode". In ECM, the Q-input may be selected via the DEQ Bit (Addr: 0h, Bit: 6), a.k.a. "DESQ Mode". In ECM, both the I- and Q-inputs maybe selected, a.k.a. "DESIQ Mode".

To use this feature in ECM, use the DES bit in the Configuration Register (Addr: 0h; Bit: 7). See [Section 17.3.1.4 DES/Non-DES Mode](#) for more information.

#### 17.2.1.2 Non-Demultiplexed Mode Pin (NDM)

The Non-Demultiplexed Mode (NDM) Pin selects whether the ADC12D2000RF is in Demux Mode (logic-low) or Non-Demux Mode (logic-high). In Non-Demux Mode, the data from the input is produced at the sampled rate at a single 12-bit output bus. In Demux Mode, the data from the input is produced at half the sampled rate at twice the number of output buses. For Non-DES Mode, each I- or Q-channel will produce its data on one or two buses for Non-Demux or Demux Mode, respectively. For DES Mode, the selected channel will produce its data on two or four buses for Non-Demux or Demux Mode, respectively.

This feature is pin-controlled only and remains active during both Non-ECM and ECM. See [Section 17.3.2.5 Demux/Non-demux Mode](#) for more information.

#### 17.2.1.3 Dual Data Rate Phase Pin (DDRPh)

The Dual Data Rate Phase (DDRPh) Pin selects whether the ADC12D2000RF is in 0° Mode (logic-low) or 90° Mode (logic-high) for DDR Mode. If the device is in SDR Mode, then the DDRPh Pin selects whether the ADC12D2000RF is in Falling Mode (logic low) or Rising Mode (logic high). For DDR Mode, the Data may transition either with the DCLK transition (0° Mode) or halfway between DCLK transitions (90° Mode). The DDRPh Pin selects 0° Mode or 90° Mode for both the I-channel: DI- and DI<sub>d</sub>-to-DCLKI phase relationship and for the Q-channel: DQ- and DQ<sub>d</sub>-to-DCLKQ phase relationship.

To use this feature in ECM, use the DPS bit in the Configuration Register (Addr: 0h; Bit: 14). See [Section 17.3.2.1 SDR/DDR Clock](#) for more information.

#### 17.2.1.4 Calibration Pin (CAL)

The Calibration (CAL) Pin may be used to execute an on-command calibration or to disable the power-on calibration. The effect of calibration is to maximize the dynamic performance. To initiate an on-command calibration via the CAL pin, bring the CAL pin high for a minimum of  $t_{CAL\_H}$  input clock cycles after it has been low for a minimum of  $t_{CAL\_L}$  input clock cycles. Holding the CAL pin high upon power-on will prevent execution of the power-on calibration. In ECM, this pin remains active and is logically OR'd with the CAL bit.

To use this feature in ECM, use the CAL bit in the Configuration Register (Addr: 0h; Bit: 15). See [Section 17.3.3 Calibration Feature](#) for more information.

#### 17.2.1.5 Calibration Delay Pin (CalDly)

The Calibration Delay (CalDly) Pin selects whether a shorter or longer delay time is present, after the application of power, until the start of the power-on calibration. The actual delay time is specified as  $t_{CalDly}$  and may be found in [Table 15](#). This feature is pin-controlled only and remains active in ECM. It is recommended to select the desired delay time prior to power-on and not dynamically alter this selection.

See [Section 17.3.3 Calibration Feature](#) for more information.

#### 17.2.1.6 Power Down I-channel Pin (PDI)

The Power Down I-channel (PDI) Pin selects whether the I-channel is powered down (logic-high) or active (logic-low). The digital data output pins, DI and DI<sub>d</sub>, (both positive and negative) are put into a high impedance state when the I-channel is powered down. Upon return to the active state, the pipeline will contain meaningless information and must be flushed. The supply currents (typicals and limits) are available for the I-channel powered down or active and may be found in [Table 12](#). The device should be recalibrated following a power-cycle of PDI (or PDQ).

This pin remains active in ECM. In ECM, either this pin or the PDI bit (Addr: 0h; Bit: 11) in the Control Register may be used

to power-down the I-channel. See [Section 17.3.4 Power Down](#) for more information.

#### 17.2.1.7 Power Down Q-channel Pin (PDQ)

The Power Down Q-channel (PDQ) Pin selects whether the Q-channel is powered down (logic-high) or active (logic-low). This pin functions similarly to the PDI pin, except that it applies to the Q-channel. The PDI and PDQ pins function independently of each other to control whether each I- or Q-channel is powered down or active.

This pin remains active in ECM. In ECM, either this pin or the PDQ bit (Addr: 0h; Bit: 10) in the Control Register may be used to power-down the Q-channel. See [Section 17.3.4 Power Down](#) for more information.

#### 17.2.1.8 Test Pattern Mode Pin (TPM)

The Test Pattern Mode (TPM) Pin selects whether the output of the ADC12D2000RF is a test pattern (logic-high) or the converted analog input (logic-low). The ADC12D2000RF can provide a test pattern at the four output buses independently of the input signal to aid in system debug. In TPM, the ADC is disengaged and a test pattern generator is connected to the outputs, including ORI and ORQ. See [Section 17.3.2.6 Test Pattern Mode](#) for more information.

#### 17.2.1.9 Full-Scale Input Range Pin (FSR)

The Full-Scale Input Range (FSR) Pin sets the full-scale input range for both the I- and Q-channel; for the ADC12D2000RF, only the logic-high setting is available. The input full-scale range is specified as  $V_{IN\_FSR}$  in [Table 8](#). In Non-ECM, the full-scale input range for each I- and Q-channel may not be set independently, but it is possible to do so in ECM. The device must be calibrated following a change in FSR to obtain optimal performance.

To use this feature in ECM, use the Configuration Registers (Addr: 3h and Bh). See [Section 17.3.1 Input Control and Adjust](#) for more information.

#### 17.2.1.10 AC / DC-Coupled Mode Pin ( $V_{CMO}$ )

The  $V_{CMO}$  Pin serves a dual purpose. When functioning as an output, it provides the optimal common-mode voltage for the DC-coupled analog inputs. When functioning as an input, it selects whether the device is AC-coupled (logic-low) or DC-coupled (floating). This pin is always active, in both ECM and Non-ECM.

#### 17.2.1.11 LVDS Output Common-mode Pin ( $V_{BG}$ )

The  $V_{BG}$  Pin serves a dual purpose. When functioning as an output, it provides the bandgap reference. When functioning as an input, it selects whether the LVDS output common-mode voltage is higher (logic-high) or lower (floating). The LVDS output common-mode voltage is specified as  $V_{OS}$  and may be found in [Table 11](#). This pin is always active, in both ECM and Non-ECM.

### 17.2.2 Extended Control Mode

In Extended Control Mode (ECM), most functions are controlled via the Serial Interface. In addition to this, several of the control pins remain active. See [Table 19](#) for details. ECM is selected by setting the ECE Pin to logic-low. If the ECE Pin is set to logic-high (Non-ECM), then the registers are reset to their default values. So, a simple way to reset the registers is by toggling the ECE pin. Four pins on the ADC12D2000RF control the Serial Interface:  $\overline{SCS}$ , SCLK, SDI and SDO. This section covers the Serial Interface. The Register Definitions are located at the end of the datasheet so that they are easy to find, see [Section 19.0 Register Definitions](#).

#### 17.2.2.1 The Serial Interface

The ADC12D2000RF offers a Serial Interface that allows access to the sixteen control registers within the device. The Serial Interface is a generic 4-wire (optionally 3-wire) synchronous interface that is compatible with SPI type interfaces that are used on many micro-controllers and DSP controllers. Each serial interface access cycle is exactly 24 bits long. A register-read or register-write can be accomplished in one cycle. The signals are defined in such a way that the user can opt to simply join SDI and SDO signals in his system to accomplish a single, bidirectional SDI/O signal. A summary of the pins for this interface may be found in [Table 17](#). See [Figure 10](#) for the timing diagram and [Table 14](#) for timing specification details. Control register contents are retained when the device is put into power-down mode. If this feature is unused, the SCLK, SDI, and  $\overline{SCS}$  pins may be left floating because they each have an internal pull-up.

**TABLE 17. Serial Interface Pins**

Pin	Name
C4	$\overline{SCS}$ (Serial Chip Select bar)
C5	SCLK (Serial Clock)
B4	SDI (Serial Data In)
A3	SDO (Serial Data Out)

**SCS:** Each assertion (logic-low) of this signal starts a new register access, i.e. the SDI command field must be ready on the following SCLK rising edge. The user is required to de-assert this signal after the 24th clock. If the  $\overline{SCS}$  is de-asserted before the 24th clock, no data read / write will occur. For a read operation, if the  $\overline{SCS}$  is asserted longer than 24 clocks, the SDO output will hold the D0 bit until  $\overline{SCS}$  is de-asserted. For a write operation, if the  $\overline{SCS}$  is asserted longer

than 24 clocks, data write will occur normally through the SDI input upon the 24th clock. Setup and hold times,  $t_{SCS}$  and  $t_{HCS}$ , with respect to the SCLK must be observed.  $\overline{SCS}$  must be toggled in between register access cycles.

**SCLK:** This signal is used to register the input data (SDI) on the rising edge; and to source the output data (SDO) on the falling edge. The user may disable the clock and hold it at logic-low. There is no minimum frequency requirement for SCLK; see  $f_{SCLK}$  in [Table 14](#) for more details.

**SDI:** Each register access requires a specific 24-bit pattern at this input, consisting of a command field and a data field. If the SDI and SDO wired are shared (3-wire mode), then during read operations it is necessary to tri-state the master which is driving SDI while the data field is being output by the ADC on SDO. The master must be at TRI-STATE before the falling edge of the 8th clock. If SDI and SDO are not shared (4-wire mode), then this is not necessary. Setup and hold times,  $t_{SH}$  and  $t_{SSU}$ , with respect to the SCLK must be observed.

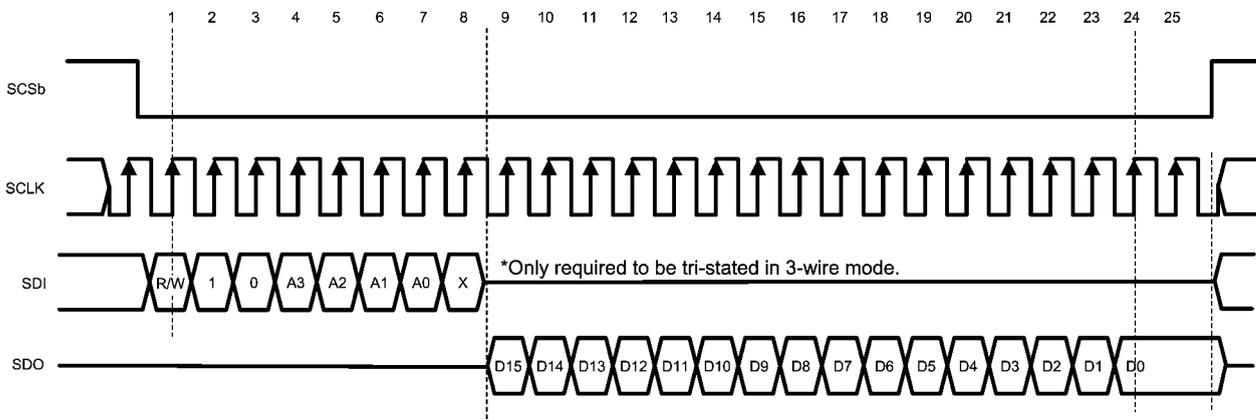

**SDO:** This output is normally at TRI-STATE and is driven only when  $\overline{SCS}$  is asserted, the first 8 bits of command data have been received and it is a READ operation. The data is shifted out, MSB first, starting with the 8th clock's falling edge. At the end of the access, when  $\overline{SCS}$  is de-asserted, this output is at TRI-STATE once again. If an invalid address is accessed, the data sourced will consist of all zeroes. If it is a read operation, there will be a bus turnaround time,  $t_{BSU}$ , from when the last bit of the command field was read in until the first bit of the data field is written out.

[Table 18](#) shows the Serial Interface bit definitions.

**TABLE 18. Command and Data Field Definitions**

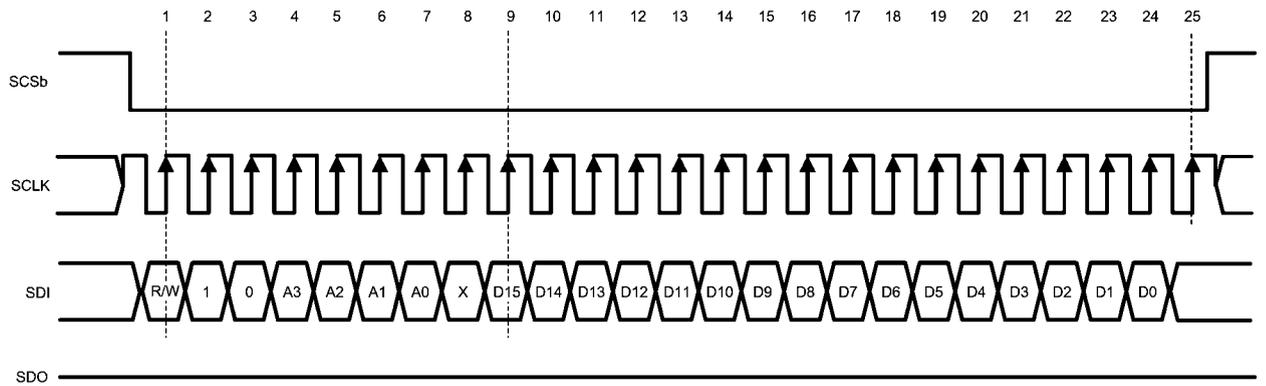

Bit No.	Name	Comments
1	Read / Write (R/W)	1b indicates a read operation 0b indicates a write operation
2-3	Reserved	Bits must be set to 10b
4-7	A<3:0>	16 registers may be addressed. The order is MSB first
8	X	This is a "don't care" bit
9-24	D<15:0>	Data written to or read from addressed register

The serial data protocol is shown for a read and write operation in [Figure 11](#) and [Figure 12](#), respectively.

17.3 FEATURES

The ADC12D2000RF offers many features to make the device convenient to use in a wide variety of applications. [Table](#)

[19](#) is a summary of the features available, as well as details for the control mode chosen. "N/A" means "Not Applicable."

TABLE 19. Features and Modes

Feature	Non-ECM	Control Pin Active in ECM	ECM	Default ECM State
<b>Input Control and Adjust</b>				
AC/DC-coupled Mode Selection	Selected via $V_{CMO}$ (Pin C2)	Yes	Not available	N/A
Input Full-scale Range Adjust	Selected via FSR (Pin Y3)	No	Selected via the Config Reg (Addr: 3h and Bh)	Low FSR value
Input Offset Adjust Setting	Not available	N/A	Selected via the Config Reg (Addr: 2h and Ah)	Offset = 0 mV
DES/Non-DES Mode Selection	Selected via DES (Pin V5)	No	Selected via the DES Bit (Addr: 0h; Bit: 7)	Non-DES Mode
DES Mode Input Selection	Not available	N/A	Selected via the DCK Bit (Addr: Eh; Bit: 6)	N/A
DESCLKIQ Mode ( <a href="#">Note 18</a> )	Not available	N/A	Selected via the DES Timing Adjust Reg (Addr: 7h)	N/A
DES Timing Adjust	Not available	N/A	Selected via the DES Timing Adjust Reg (Addr: 7h)	Mid skew offset
Sampling Clock Phase Adjust	Not available	N/A	Selected via the Config Reg (Addr: Ch and Dh)	$t_{AD}$ adjust disabled
<b>Output Control and Adjust</b>				
DDR Clock Phase Selection	Selected via DDRPh (Pin W4)	No	Selected via the DPS Bit (Addr: 0h; Bit: 14)	0° Mode
DDR / SDR DCLK Selection	Not available	N/A	Selected via the SDR Bit (Addr: 0h; Bit: 2)	DDR Mode
SDR Rising / Falling DCLK Selection ( <a href="#">Note 18</a> )	Not available	N/A	Selected via the DPS Bit (Addr: 0h; Bit: 14)	N/A
LVDS Differential Voltage Amplitude Selection	Higher amplitude only	N/A	Selected via the OVS Bit (Addr: 0h; Bit: 13)	Higher amplitude
LVDS Common-Mode Voltage Amplitude Selection ( <a href="#">Note 18</a> )	Selected via $V_{BG}$ (Pin B1)	Yes	Not available	N/A

Feature	Non-ECM	Control Pin Active in ECM	ECM	Default ECM State
<b>Output Formatting Selection</b> (Note 18)	Offset Binary only	N/A	Selected via the 2SC Bit (Addr: 0h; Bit: 4)	Offset Binary
<b>Test Pattern Mode at Output</b>	Selected via TPM (Pin A4)	No	Selected via the TPM Bit (Addr: 0h; Bit: 12)	TPM disabled
<b>Demux/Non-Demux Mode Selection</b>	Selected via NDM (Pin A5)	Yes	Not available	N/A
<b>DCLK Reset</b>	Not available	N/A	Selected via the Config Reg (Addr: Eh; Bit 0)	DCLK Reset disabled
<b>Time Stamp</b>	Not available	N/A	Selected via the TSE Bit (Addr: 0h; Bit: 3)	Time Stamp disabled
<b>Calibration</b>				
<b>On-command Calibration</b>	Selected via CAL (Pin D6)	Yes	Selected via the CAL Bit (Addr: 0h; Bit: 15)	N/A (CAL = 0)
<b>Power-on Calibration Delay Selection</b> (Note 18)	Selected via CalDly (Pin V4)	Yes	Not available	N/A
<b>Calibration Adjust</b> (Note 18)	Not available	N/A	Selected via the Config Reg (Addr: 4h)	$t_{CAL}$
<b>Read / Write Calibration Settings</b> (Note 18)	Not available	N/A	Selected via the SSC Bit (Addr: 4h; Bit: 7)	R/W calibration values disabled
<b>Power-Down</b>				
<b>Power down I-channel</b>	Selected via PDI (Pin U3)	Yes	Selected via the PDI Bit (Addr: 0h; Bit: 11)	I-channel operational
<b>Power down Q-channel</b>	Selected via PDQ (Pin V3)	Yes	Selected via the PDQ Bit (Addr: 0h; Bit: 10)	Q-channel operational

### 17.3.1 Input Control and Adjust

There are several features and configurations for the input of the ADC12D2000RF so that it may be used in many different applications. This section covers AC/DC-coupled Mode, input full-scale range adjust, input offset adjust, DES/Non-DES Mode, DES Timing Adjust, and sampling clock phase adjust.

#### 17.3.1.1 AC/DC-coupled Mode

The analog inputs may be AC or DC-coupled. See [Section 17.2.1.10 AC / DC-Coupled Mode Pin \( \$V\_{CMO}\$ \)](#) for information on how to select the desired mode and [Section 18.1.7 DC-coupled Input Signals](#) and [Section 18.1.6 AC-coupled Input Signals](#) for applications information.

#### 17.3.1.2 Input Full-Scale Range Adjust

The input full-scale range for the ADC12D2000RF may be adjusted in ECM. In Non-ECM, the control pin must be set to logic-high; see [Section 17.2.1.9 Full-Scale Input Range Pin \(FSR\)](#). In ECM, the input full-scale range may be adjusted with 15-bits of precision. See  $V_{IN\_FSR}$  in [Table 8](#) for electrical specification details. Note that the full-scale input range setting in Non-ECM (logic-high only) corresponds to the lowest full-scale input range settings in ECM. It is necessary to execute an on-command calibration following a change of the input full-scale range. See [Section 19.0 Register Definitions](#) for information about the registers.

#### 17.3.1.3 Input Offset Adjust

The input offset adjust for the ADC12D2000RF may be adjusted with 12-bits of precision plus sign via ECM. See [Section 19.0 Register Definitions](#) for information about the registers.

#### 17.3.1.4 DES/Non-DES Mode

The ADC12D2000RF can operate in Dual-Edge Sampling (DES) or Non-DES Mode. The DES Mode allows for a single analog input to be sampled by both I- and Q-channels. One channel samples the input on the rising edge of the sampling clock and the other samples the same input signal on the falling edge of the sampling clock. A single input is thus sampled twice per clock cycle, resulting in an overall sample rate of twice the sampling clock frequency, e.g. 4.0 GSPS with a 2.0 GHz sampling clock. Since DES Mode uses both I- and Q-channels to process the input signal, both channels must be powered up for the DES Mode to function properly.

In Non-ECM, only the I-input may be used for the DES Mode input. See [Section 17.2.1.1 Dual Edge Sampling Pin \(DES\)](#) for information on how to select the DES Mode. In ECM, either the I- or Q-input may be selected by first using the DES bit (Addr: 0h, Bit 7) to select the DES Mode. The DEQ Bit (Addr: 0h, Bit: 6) is used to select the Q-input, but the I-input is used by default. Also, both I- and Q-inputs may be driven externally, i.e. DESIQ Mode, by using the DIQ bit (Addr: 0h, Bit 5). See [Section 18.1 THE ANALOG INPUTS](#) for more information about how to drive the ADC in DES Mode.

In DESCLKIQ Mode, the I- and Q-channels sample their inputs 180° out-of-phase with respect to one another, similar to the other DES Modes. DESCLKIQ Mode is similar to the DESIQ Mode, except that the I- and Q-channels remain electrically separate internal to the ADC12D2000RF. For this reason, both I- and Q-inputs must be externally driven for the DESCLKIQ Mode. The DCLK Bit (Addr: Eh, Bit 6) is used to select the 180° sampling clock mode.

The DESCLKIQ Mode results in the best bandwidth for the interleaved modes. In general, the bandwidth decreases from

Non-DES Mode to DES Mode (specifically, DESI or DESQ) because both channels are sampling off the same input signal and non-ideal effects introduced by interleaving the two channels lower the bandwidth. Driving both I- and Q-channels externally (DESIQ Mode and DESCLKIQ Mode) results in better bandwidth for the DES Mode because each channel is being driven, which reduces routing losses. The DESCLKIQ Mode has better bandwidth than the DESIQ Mode because the routing internal to the ADC12D2000RF is simpler, which results in less insertion loss.

In the DES Mode, the outputs must be carefully interleaved in order to reconstruct the sampled signal. If the device is programmed into the 1:4 Demux DES Mode, the data is effectively demultiplexed by 1:4. If the sampling clock is 2.0 GHz, the effective sampling rate is doubled to 4.0 GSPS and each of the 4 output buses has an output rate of 1.0 GSPS. All data is available in parallel. To properly reconstruct the sampled waveform, the four bytes of parallel data that are output with each DCLK must be correctly interleaved. The sampling order is as follows, from the earliest to the latest: DQd, DI, DQ, DI. See [Figure 6](#). If the device is programmed into the Non-Demux DES Mode, two bytes of parallel data are output with each edge of the DCLK in the following sampling order, from the earliest to the latest: DQ, DI. See [Figure 7](#).

**17.3.1.5 DES Timing Adjust**

The performance of the ADC12D2000RF in DES Mode depends on how well the two channels are interleaved, i.e. that the clock samples either channel with precisely a 50% duty-cycle, each channel has the same offset (nominally code 2047/2048), and each channel has the same full-scale range. The ADC12D2000RF includes an automatic clock phase background adjustment in DES Mode to automatically and continuously adjust the clock phase of the I- and Q-channels. In addition to this, the residual fixed timing skew offset may be further manually adjusted, and further reduce timing spurs for specific applications. See the DES Timing Adjust (Addr: 7h). As the DES Timing Adjust is programmed from 0d to 127d, the magnitude of the  $F_s/2$ -Fin timing interleaving spur will decrease to a local minimum and then increase again. The default, nominal setting of 64d may or may not coincide with this local minimum. The user may manually skew the global timing to achieve the lowest possible timing interleaving spur.

**17.3.1.6 Sampling Clock Phase Adjust**

The sampling clock (CLK) phase may be delayed internally to the ADC up to 825 ps in ECM. This feature is intended to help the system designer remove small imbalances in clock distribution traces at the board level when multiple ADCs are used, or to simplify complex system functions such as beam steering for phase array antennas.

Additional delay in the clock path also creates additional jitter when using the sampling clock phase adjust. Because the sampling clock phase adjust delays all clocks, including the DCLKs and output data, the user is strongly advised to use the minimal amount of adjustment and verify the net benefit of this feature in his system before relying on it.

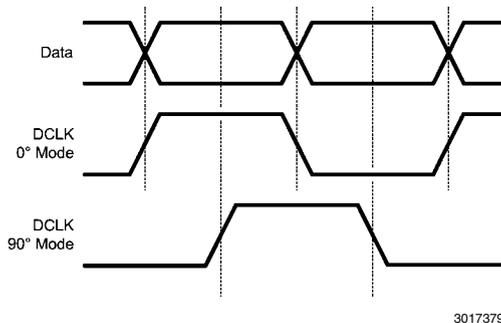

Using this feature at its maximum setting, for the maximum sampling clock rate, may affect the integrity of the sampling clock on chip. Therefore, it is not recommended to do so. The maximum setting for the coarse adjust is 825ps. The period for the maximum sampling clock rate is 500ps, so it should not be necessary to exceed this value in any case.

**17.3.2 Output Control and Adjust**

There are several features and configurations for the output of the ADC12D2000RF so that it may be used in many different applications. This section covers DDR clock phase, LVDS output differential and common-mode voltage, output formatting, Demux/Non-demux Mode, Test Pattern Mode, and Time Stamp.

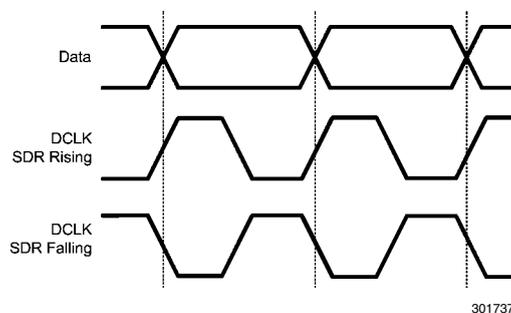

**17.3.2.1 SDR / DDR Clock**

The ADC12D2000RF output data can be delivered in Double Data Rate (DDR) or Single Data Rate (SDR). For DDR, the DCLK frequency is half the data rate and data is sent to the outputs on both edges of DCLK; see [Figure 13](#). The DCLK-to-Data phase relationship may be either 0° or 90°. For 0° Mode, the Data transitions on each edge of the DCLK. Any offset from this timing is  $t_{OSK}$ ; see [Table 13](#) for details. For 90° Mode, the DCLK transitions in the middle of each Data cell. Setup and hold times for this transition,  $t_{SU}$  and  $t_H$ , may also be found in [Table 13](#). The DCLK-to-Data phase relationship may be selected via the DDRPh Pin in Non-ECM (see [Section 17.2.1.3 Dual Data Rate Phase Pin \(DDRPh\)](#)) or the DPS bit in the Configuration Register (Addr: 0h; Bit: 14) in ECM. Note that for Non-Demux Mode, 90° DDR Mode is not available.

**FIGURE 13. DDR DCLK-to-Data Phase Relationship**

For SDR, the DCLK frequency is the same as the data rate and data is sent to the outputs on a single edge of DCLK; see [Figure 14](#). The Data may transition on either rising or falling edge of DCLK. Any offset from this timing is  $t_{OSK}$ ; see [Table 13](#) for details. The DCLK rising / falling edge may be selected via the SDR bit in the Configuration Register (Addr: 0h; Bit: 2) in ECM only. Note that SDR is available in Demux Mode, but not in Non-Demux Mode.

**FIGURE 14. SDR DCLK-to-Data Phase Relationship**

### 17.3.2.2 LVDS Output Differential Voltage

The ADC12D2000RF is available with a selectable higher or lower LVDS output differential voltage. This parameter is  $V_{OD}$  and may be found in [Table 11](#). The desired voltage may be selected via the OVS Bit (Addr: 0h, Bit 13). For many applications, in which the LVDS outputs are very close to an FPGA on the same board, for example, the lower setting is sufficient for good performance; this will also reduce the possibility for EMI from the LVDS outputs to other signals on the board. See [Section 19.0 Register Definitions](#) for more information.

### 17.3.2.3 LVDS Output Common-Mode Voltage

The ADC12D2000RF is available with a selectable higher or lower LVDS output common-mode voltage. This parameter is  $V_{OS}$  and may be found in [Table 11](#). See [Section 17.2.1.11 LVDS Output Common-mode Pin \( \$V\_{BG}\$ \)](#) for information on how to select the desired voltage.

### 17.3.2.4 Output Formatting

The formatting at the digital data outputs may be either offset binary or two's complement. The default formatting is offset binary, but two's complement may be selected via the 2SC Bit (Addr: 0h, Bit 4); see [Section 19.0 Register Definitions](#) for more information.

### 17.3.2.5 Demux/Non-demux Mode

The ADC12D2000RF may be in one of two demultiplex modes: Demux Mode or Non-Demux Mode (also sometimes referred to as 1:1 Demux Mode). In Non-Demux Mode, the data from the input is simply output at the sampling rate on one 12-bit bus. In Demux Mode, the data from the input is output at half the sampling rate, on twice the number of buses. Demux/Non-Demux Mode may only be selected by the NDM pin; see [Section 17.2.1.2 Non-Demultiplexed Mode Pin \(NDM\)](#). In Non-DES Mode, the output data from each channel may be demultiplexed by a factor of 1:2 (1:2 Demux Non-DES Mode) or not demultiplexed (Non-Demux Non-DES Mode). In DES Mode, the output data from both channels interleaved may be demultiplexed (1:4 Demux DES Mode) or not demultiplexed (Non-Demux DES Mode).

Note that for Non-Demux Mode, 90° DDR Mode and SDR Mode are not available. See [Table 20](#) for a selection of available modes.

**TABLE 20. Supported Demux, Data Rate Modes**

	Non-Demux Mode	1:2 Demux Mode
DDR	0° Mode only	0° Mode / 90° Mode
SDR	Not Available	Rising / Falling Mode

### 17.3.2.6 Test Pattern Mode

The ADC12D2000RF can provide a test pattern at the four output buses independently of the input signal to aid in system debug. In Test Pattern Mode, the ADC is disengaged and a test pattern generator is connected to the outputs, including ORI and ORQ. The test pattern output is the same in DES Mode or Non-DES Mode. Each port is given a unique 12-bit word, alternating between 1's and 0's. When the part is programmed into the Demux Mode, the test pattern's order is described in [Table 21](#). If the I- or Q-channel is powered down, the test pattern will not be output for that channel.

**TABLE 21. Test Pattern by Output Port in Demux Mode**

Time	Qd	Id	Q	I	ORQ	ORI	Comments

### 17.3.2.7 Time Stamp

The Time Stamp feature enables the user to capture the timing of an external trigger event, relative to the sampled signal. When enabled via the TSE Bit (Addr: 0h; Bit: 3), the LSB of the digital outputs (DQd, DQ, DId, DI) captures the trigger information. In effect, the 12-bit converter becomes an 11-bit converter and the LSB acts as a 1-bit converter with the same latency as the 11-bit converter. The trigger should be applied to the DCLK\_RST input. It may be asynchronous to the ADC sampling clock.

### 17.3.3 Calibration Feature

The ADC12D2000RF calibration must be run to achieve specified performance. The calibration procedure is exactly the same regardless of how it was initiated or when it is run. Calibration trims the analog input differential termination resistors, the CLK input resistor, and sets internal bias currents which affect the linearity of the converter. This minimizes full-

scale error, offset error, DNL and INL, which results in the maximum dynamic performance, as measured by: SNR, THD, SINAD (SNDR) and ENOB.

### 17.3.3.1 Calibration Control Pins and Bits

Table 23 is a summary of the pins and bits used for calibration. See Section 9.0 Ball Descriptions and Equivalent Circuits for complete pin information and Figure 9 for the timing diagram.

TABLE 23. Calibration Pins

Pin (Bit)	Name	Function
D6 (Addr: 0h; Bit 15)	CAL (Calibration)	Initiate calibration
V4	CalDly (Calibration Delay)	Select power-on calibration delay
(Addr: 4h)	Calibration Adjust	Adjust calibration sequence
B5	CalRun (Calibration Running)	Indicates while calibration is running
C1/D2	Rtrim+/- (Input termination trim resistor)	External resistor used to calibrate analog and CLK inputs
C3/D3	Rext+/- (External Reference resistor)	External resistor used to calibrate internal linearity

### 17.3.3.2 How to Execute a Calibration

Calibration may be initiated by holding the CAL pin low for at least  $t_{CAL\_L}$  clock cycles, and then holding it high for at least another  $t_{CAL\_H}$  clock cycles, as defined in Table 15. The minimum  $t_{CAL\_L}$  and  $t_{CAL\_H}$  input clock cycle sequences are required to ensure that random noise does not cause a calibration to begin when it is not desired. The time taken by the calibration procedure is specified as  $t_{CAL}$ . The CAL Pin is active in both ECM and Non-ECM. However, in ECM, the CAL Pin is logically OR'd with the CAL Bit, so both the pin and bit are required to be set low before executing another calibration via either pin or bit.

### 17.3.3.3 Power-on Calibration

For standard operation, power-on calibration begins after a time delay following the application of power, as determined by the setting of the CalDly Pin and measured by  $t_{CalDly}$  (see Table 15). This delay allows the power supply to come up and stabilize before the power-on calibration takes place. The best setting (short or long) of the CalDly Pin depends upon the settling time of the power supply.

It is strongly recommended to set CalDly Pin (to either logic-high or logic-low) before powering the device on since this pin affects the power-on calibration timing. This may be accomplished by setting CalDly via an external 1k $\Omega$  resistor connected to GND or  $V_A$ . If the CalDly Pin is toggled while the device is powered-on, it can execute a calibration even though the CAL Pin / Bit remains logic-low.

The power-on calibration will be not be performed if the CAL pin is logic-high at power-on. In this case, the calibration cycle will not begin until the on-command calibration conditions are met. The ADC12D2000RF will function with the CAL pin held

high at power up, but no calibration will be done and performance will be impaired.

If it is necessary to toggle the CalDly Pin during the system power up sequence, then the CAL Pin / Bit must be set to logic-high before the toggling and afterwards for  $10^9$  Sampling Clock cycles. This will prevent the power-on calibration, so an on-command calibration must be executed or the performance will be impaired.

### 17.3.3.4 On-command Calibration

In addition to the power-on calibration, it is recommended to execute an on-command calibration whenever the settings or conditions to the device are altered significantly, in order to obtain optimal parametric performance. Some examples include: changing the FSR via ECM, power-cycling either channel, and switching into or out of DES Mode. For best performance, it is also recommended that an on-command calibration be run 20 seconds or more after application of power and whenever the operating temperature changes significantly, relative to the specific system performance requirements.

Due to the nature of the calibration feature, it is recommended to avoid unnecessary activities on the device while the calibration is taking place. For example, do not read or write to the Serial Interface or use the DCLK Reset feature while calibrating the ADC. Doing so will impair the performance of the device until it is re-calibrated correctly. Also, it is recommended to not apply a strong narrow-band signal to the analog inputs during calibration because this may impair the accuracy of the calibration; broad spectrum noise is acceptable.

### 17.3.3.5 Calibration Adjust

The sequence of the calibration event itself may be adjusted. This feature can be used if a shorter calibration time than the default is required; see  $t_{CAL}$  in Table 15. However, the performance of the device, when using this feature is not guaranteed.

The calibration sequence may be adjusted via CSS (Addr: 4h, Bit 14). The default setting of CSS = 1b executes both  $R_{IN}$  and  $R_{IN\_CLK}$  Calibration (using Rtrim) and internal linearity Calibration (using Rext). Executing a calibration with CSS = 0b executes only the internal linearity Calibration. The first time that Calibration is executed, it must be with CSS = 1b to trim  $R_{IN}$  and  $R_{IN\_CLK}$ . However, once the device is at its operating temperature and  $R_{IN}$  has been trimmed at least one time, it will not drift significantly. To save time in subsequent calibrations, trimming  $R_{IN}$  and  $R_{IN\_CLK}$  may be skipped, i.e. by setting CSS = 0b.

### 17.3.3.6 Read / Write Calibration Settings

When the ADC performs a calibration, the calibration constants are stored in an array which is accessible via the Calibration Values register (Addr: 5h). To save the time which it takes to execute a calibration,  $t_{CAL}$ , or to allow for re-use of a previous calibration result, these values can be read from and written to the register at a later time. For example, if an application requires the same input impedance,  $R_{IN}$ , this feature can be used to load a previously determined set of values. For the calibration values to be valid, the ADC must be operating under the same conditions, including temperature, at which the calibration values were originally determined by the ADC.

To read calibration values from the SPI, do the following:

1. Set ADC to desired operating conditions.
2. Set SSC (Addr: 4h, Bit 7) to 1.
3. Power down both I- and Q-channels.

4. Read exactly 240 times the Calibration Values register (Addr: 5h). The register values are R0, R1, R2... R239. The contents of R<239:0> should be stored.
5. Power up I- and Q-channels to original setting.
6. Set SSC (Addr: 4h, Bit 7) to 0.
7. Continue with normal operation.

To write calibration values to the SPI, do the following:

1. Set ADC to operating conditions at which Calibration Values were previously read.
2. Set SSC (Addr: 4h, Bit 7) to 1.
3. Power down both I- and Q-channels.
4. Write exactly 240 times the Calibration Values register (Addr: 5h). The registers should be written R0, R1... R239.
5. Make two additional dummy writes of 0000h.
6. Power up I- and Q-channels to original setting.
7. Set SSC (Addr: 4h, Bit 7) to 0.
8. Continue with normal operation.

#### 17.3.3.7 Calibration and Power-Down

If PDI and PDQ are simultaneously asserted during a calibration cycle, the ADC12D2000RF will immediately power down. The calibration cycle will continue when either or both channels are powered back up, but the calibration will be compromised due to the incomplete settling of bias currents

directly after power up. Therefore, a new calibration should be executed upon powering the ADC12D2000RF back up. In general, the ADC12D2000RF should be recalibrated when either or both channels are powered back up, or after one channel is powered down. For best results, this should be done after the device has stabilized to its operating temperature.

#### 17.3.3.8 Calibration and the Digital Outputs

During calibration, the digital outputs (including DI, DI<sub>d</sub>, DQ, DQ<sub>d</sub> and OR) are set logic-low, to reduce noise. The DCLK runs continuously during calibration. After the calibration is completed and the CalRun signal is logic-low, it takes an additional 60 Sampling Clock cycles before the output of the ADC12D2000RF is valid converted data from the analog inputs. This is the time it takes for the pipeline to flush, as well as for other internal processes.

#### 17.3.4 Power Down

On the ADC12D2000RF, the I- and Q-channels may be powered down individually. This may be accomplished via the control pins, PDI and PDQ, or via ECM. In ECM, the PDI and PDQ pins are logically OR'd with the Control Register setting. See [Section 17.2.1.6 Power Down I-channel Pin \(PDI\)](#) and [Section 17.2.1.7 Power Down Q-channel Pin \(PDQ\)](#) for more information.

## 18.0 Applications Information

### 18.1 THE ANALOG INPUTS

The ADC12D2000RF will continuously convert any signal which is present at the analog inputs, as long as a CLK signal is also provided to the device. This section covers important aspects related to the analog inputs including: acquiring the input, driving the ADC in DES Mode, the reference voltage and FSR, out-of-range indication, AC/DC-coupled signals, and single-ended input signals.

#### 18.1.1 Acquiring the Input

The Aperture Delay,  $t_{AD}$ , is the amount of delay, measured from the sampling edge of the clock input, after which the signal present at the input pin is sampled inside the device. Data is acquired at the rising edge of CLK+ in Non-DES Mode and both the falling and rising edge of CLK+ in DES Mode. In Non-DES Mode, the I- and Q-channels always sample data on the rising edge of CLK+. In DES Mode, i.e. DESI, DESQ, DESIQ, and DESCLKIQ, the I-channel samples data on the rising edge of CLK+ and the Q-channel samples data on the falling edge of CLK+. The digital equivalent of that data is available at the digital outputs a constant number of sampling clock cycles later for the DI, DQ, DI<sub>d</sub> and DQ<sub>d</sub> output busses, a.k.a. the latency, depending on the demultiplex mode which is selected. In addition to the latency, there is a constant output delay,  $t_{OD}$ , before the data is available at the outputs. See  $t_{OD}$  in the Timing Diagrams. See  $t_{LAT}$ ,  $t_{AD}$ , and  $t_{OD}$  in [Table 13](#).

#### 18.1.2 Driving the ADC in DES Mode

The ADC12D2000RF can be configured as either a 2-channel, 2.0 GSPS device (Non-DES Mode) or a 1-channel 4.0 GSPS device (DES Mode). When the device is configured in DES Mode, there is a choice for with which input to drive the single-channel ADC. These are the 3 options:

DES – externally driving the I-channel input only. This is the default selection when the ADC is configured in DES Mode. It may also be referred to as “DESI” for added clarity.

DESQ – externally driving the Q-channel input only.

DESIQ, DESCLKIQ – externally driving both the I- and Q-channel inputs. VinI+ and VinQ+ should be driven with the exact same signal. VinI- and VinQ- should be driven with the exact same signal, which is the differential complement to the one driving VinI+ and VinQ+.

The input impedance for each I- and Q-input is 100Ω differential (or 50Ω single-ended), so the trace to each VinI+, VinI-, VinQ+, and VinQ- should always be 50Ω single-ended. If a single I- or Q-input is being driven, then that input will present a 100Ω differential load. For example, if a 50Ω single-ended source is driving the ADC, then a 1:2 balun will transform the impedance to 100Ω differential. However, if the ADC is being driven in DESIQ Mode, then the 100Ω differential impedance from the I-input will appear in parallel with the Q-input for a composite load of 50Ω differential and a 1:1 balun would be appropriate. See [Figure 15](#) for an example circuit driving the ADC in DESIQ Mode. A recommended part selection is using the Mini-Circuits TC1-1-13MA+ balun with  $C_{couple} = 0.22\mu F$ .

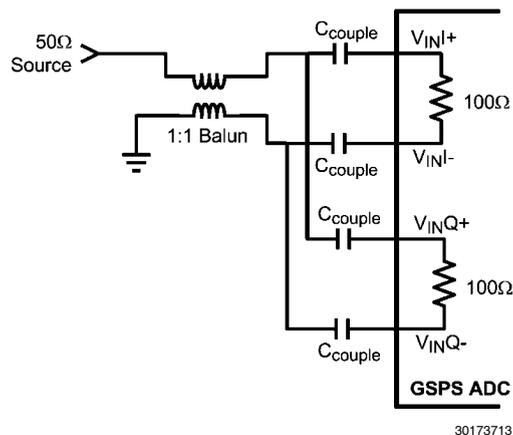

FIGURE 15. Driving DESIQ Mode

In the case that only one channel is used in Non-DES Mode or that the ADC is driven in DESI or DESQ Mode, the unused analog input should be terminated to reduce any noise coupling into the ADC. See [Table 24](#) for details.

TABLE 24. Unused Analog Input Recommended Termination

Mode	Power Down	Coupling	Recommended Termination
Non-DES	Yes	AC/DC	Tie Unused+ and Unused- to Vbg
DES/ Non-DES	No	DC	Tie Unused+ and Unused- to Vbg
DES/ Non-DES	No	AC	Tie Unused+ to Unused-

#### 18.1.3 FSR and the Reference Voltage

The full-scale analog differential input range ( $V_{IN\_FSR}$ ) of the ADC12D2000RF is derived from an internal bandgap reference. In Non-ECM, this full-scale range must be set by the logic-high setting of the FSR Pin; see [Section 17.2.1.9 Full-Scale Input Range Pin \(FSR\)](#). The FSR Pin operates on both I- and Q-channels. In ECM, the full-scale range may be independently set for each channel via Addr:3h and Bh with 15 bits of precision; see [Section 19.0 Register Definitions](#). The best SNR is obtained with a higher full-scale input range, but better distortion and SFDR are obtained with a lower full-scale input range. It is not possible to use an external analog reference voltage to modify the full-scale range, and this adjustment should only be done digitally, as described.

A buffered version of the internal bandgap reference voltage is made available at the  $V_{BG}$  Pin for the user. The  $V_{BG}$  pin can drive a load of up to 80 pF and source or sink up to 100 μA. It should be buffered if more current than this is required. This pin remains as a constant reference voltage regardless of what full-scale range is selected and may be used for a system reference.  $V_{BG}$  is a dual-purpose pin and it may also be used to select a higher LVDS output common-mode voltage; see [Section 17.2.1.11 LVDS Output Common-mode Pin \( \$V\_{BG}\$ \)](#).

#### 18.1.4 Out-Of-Range Indication

Differential input signals are digitized to 12 bits, based on the full-scale range. Signal excursions beyond the full-scale range, i.e. greater than  $+V_{IN\_FSR}/2$  or less than  $-V_{IN\_FSR}/2$ , will be clipped at the output. An input signal which is above the

FSR will result in all 1's at the output and an input signal which is below the FSR will result in all 0's at the output. When the conversion result is clipped for the I-channel input, the Out-of-Range I-channel (ORI) output is activated such that ORI+ goes high and ORI- goes low while the signal is out of range. This output is active as long as accurate data on either or both of the buses would be outside the range of 000h to FFFh. The Q-channel has a separate ORQ which functions similarly.

### 18.1.5 Maximum Input Range

The recommended operating and absolute maximum input range may be found in [Section 11.0 Operating Ratings](#) and [Section 10.0 Absolute Maximum Ratings](#), respectively. Under the stated allowed operating conditions, each  $V_{IN+}$  and  $V_{IN-}$  input pin may be operated in the range from 0V to 2.15V if the input is a continuous 100% duty cycle signal and from 0V to 2.5V if the input is a 10% duty cycle signal. The absolute maximum input range for  $V_{IN+}$  and  $V_{IN-}$  is from -0.15V to 2.5V. These limits apply only for input signals for which the input common mode voltage is properly maintained.

### 18.1.6 AC-coupled Input Signals

The ADC12D2000RF analog inputs require a precise common-mode voltage. This voltage is generated on-chip when AC-coupling Mode is selected. See [Section 17.2.1.10 AC / DC-Coupled Mode Pin \( \$V\_{CMO}\$ \)](#) for more information about how to select AC-coupled Mode.

In AC-coupled Mode, the analog inputs must of course be AC-coupled. For an ADC12D2000RF used in a typical application, this may be accomplished by on-board capacitors, as shown in [Figure 16](#). For the ADC12D2000RFRB, the SMA inputs on the Reference Board are directly connected to the analog inputs on the ADC12D2000RF, so this may be accomplished by DC blocks (included with the hardware kit).

When the AC-coupled Mode is selected, an analog input channel that is not used (e.g. in DES Mode) should be connected to AC ground, e.g. through capacitors to ground. Do not connect an unused analog input directly to ground.

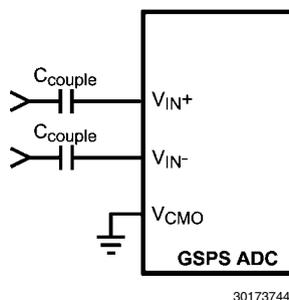

FIGURE 16. AC-coupled Differential Input

The analog inputs for the ADC12D2000RF are internally buffered, which simplifies the task of driving these inputs and the RC pole which is generally used at sampling ADC inputs is not required. If the user desires to place an amplifier circuit before the ADC, care should be taken to choose an amplifier with adequate noise and distortion performance, and adequate gain at the frequencies used for the application.

### 18.1.7 DC-coupled Input Signals

In DC-coupled Mode, the ADC12D2000RF differential inputs must have the correct common-mode voltage. This voltage is provided by the device itself at the  $V_{CMO}$  output pin. It is recommended to use this voltage because the  $V_{CMO}$  output potential will change with temperature and the common-mode

voltage of the driving device should track this change. Full-scale distortion performance falls off as the input common mode voltage deviates from  $V_{CMO}$ . Therefore, it is recommended to keep the input common-mode voltage within 100 mV of  $V_{CMO}$  (typical), although this range may be extended to  $\pm 150$  mV (maximum). See  $V_{CMI}$  in [Table 8](#) and ENOB vs.  $V_{CMI}$  in [Section 16.0 Typical Performance Plots](#). Performance in AC- and DC-coupled Mode are similar, provided that the input common mode voltage at both analog inputs remains within 100 mV of  $V_{CMO}$ .

### 18.1.8 Single-Ended Input Signals

The analog inputs of the ADC12D2000RF are not designed to accept single-ended signals. The best way to handle single-ended signals is to first convert them to differential signals before presenting them to the ADC. The easiest way to accomplish single-ended to differential signal conversion is with an appropriate balun-transformer, as shown in [Figure 17](#).

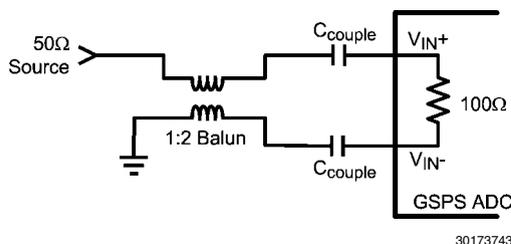

FIGURE 17. Single-Ended to Differential Conversion Using a Balun

When selecting a balun, it is important to understand the input architecture of the ADC. The impedance of the analog source should be matched to the ADC12D2000RF's on-chip 100 $\Omega$  differential input termination resistor. The range of this termination resistor is specified as  $R_{IN}$  in [Table 8](#).

## 18.2 THE CLOCK INPUTS

The ADC12D2000RF has a differential clock input, CLK+ and CLK-, which must be driven with an AC-coupled, differential clock signal. This provides the level shifting necessary to allow for the clock to be driven with LVDS, PECL, LVPECL, or CML levels. The clock inputs are internally terminated to 100 $\Omega$  differential and self-biased. This section covers coupling, frequency range, level, duty-cycle, jitter, and layout considerations.

### 18.2.1 CLK Coupling

The clock inputs of the ADC12D2000RF must be capacitively coupled to the clock pins as indicated in [Figure 18](#).

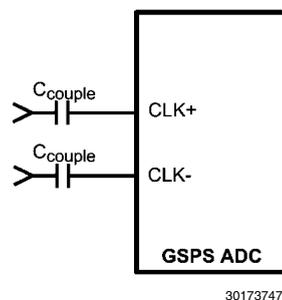

FIGURE 18. Differential Input Clock Connection

The choice of capacitor value will depend on the clock frequency, capacitor component characteristics and other system economic factors. For example, on the ADC12D2000RFRB, the capacitors have the value  $C_{\text{couple}} = 4.7 \text{ nF}$  which yields a high pass cutoff frequency,  $f_c = 677.2 \text{ kHz}$ .

### 18.2.2 CLK Frequency

Although the ADC12D2000RF is tested and its performance is guaranteed with a differential 2.0 GHz sampling clock, it will typically function well over the input clock frequency range; see  $f_{\text{CLK}}(\text{min})$  and  $f_{\text{CLK}}(\text{max})$  in [Table 13](#). Operation up to  $f_{\text{CLK}}(\text{max})$  is possible if the maximum ambient temperatures indicated are not exceeded. Operating at sample rates above  $f_{\text{CLK}}(\text{max})$  for the maximum ambient temperature may result in reduced device reliability and product lifetime. This is due to the fact that higher sample rates results in higher power consumption and die temperatures. If  $f_{\text{CLK}} < 300 \text{ MHz}$ , enable LFS in the Control Register (Addr: 0h, Bit 8).

### 18.2.3 CLK Level

The input clock amplitude is specified as  $V_{\text{IN\_CLK}}$  in [Table 10](#). Input clock amplitudes above the max  $V_{\text{IN\_CLK}}$  may result in increased input offset voltage. This would cause the converter to produce an output code other than the expected 2047/2048 when both input pins are at the same potential. Insufficient input clock levels will result in poor dynamic performance. Both of these results may be avoided by keeping the clock input amplitude within the specified limits of  $V_{\text{IN\_CLK}}$ .

### 18.2.4 CLK Duty Cycle

The duty cycle of the input clock signal can affect the performance of any A/D converter. The ADC12D2000RF features a duty cycle clock correction circuit which can maintain performance over the 20%-to-80% specified clock duty-cycle range. This feature is enabled by default and provides improved ADC clocking, especially in the Dual-Edge Sampling (DES) Mode.

### 18.2.5 CLK Jitter

High speed, high performance ADCs such as the ADC12D2000RF require a very stable input clock signal with minimum phase noise or jitter. ADC jitter requirements are defined by the ADC resolution (number of bits), maximum ADC input frequency and the input signal amplitude relative to the ADC input full scale range. The maximum jitter (the sum of the jitter from all sources) allowed to prevent a jitter-induced reduction in SNR is found to be

$$t_{\text{J(MAX)}} = (V_{\text{IN(P-P)}}/V_{\text{FSR}}) \times (1/(2^{(N+1)} \times \pi \times f_{\text{IN}}))$$

where  $t_{\text{J(MAX)}}$  is the rms total of all jitter sources in seconds,  $V_{\text{IN(P-P)}}$  is the peak-to-peak analog input signal,  $V_{\text{FSR}}$  is the full-scale range of the ADC, "N" is the ADC resolution in bits and  $f_{\text{IN}}$  is the maximum input frequency, in Hertz, at the ADC analog input.

$t_{\text{J(MAX)}}$  is the square root of the sum of the squares (RSS) sum of the jitter from all sources, including: the ADC input clock, system, input signals and the ADC itself. Since the effective

jitter added by the ADC is beyond user control, it is recommended to keep the sum of all other externally added jitter to a minimum.

### 18.2.6 CLK Layout

The ADC12D2000RF clock input is internally terminated with a trimmed 100Ω resistor. The differential input clock line pair should have a characteristic impedance of 100Ω and (when using a balun), be terminated at the clock source in that (100Ω) characteristic impedance.

It is good practice to keep the ADC input clock line as short as possible, tightly coupled, keep it well away from any other signals, and treat it as a transmission line. Otherwise, other signals can introduce jitter into the input clock signal. Also, the clock signal can introduce noise into the analog path if it is not properly isolated.

### 18.3 THE LVDS OUTPUTS

The Data, ORI, ORQ, DCLKI and DCLKQ outputs are LVDS. The electrical specifications of the LVDS outputs are compatible with typical LVDS receivers available on ASIC and FPGA chips; but they are not IEEE or ANSI communications standards compliant due to the low +2.0V supply used on this chip. These outputs should be terminated with a 100Ω differential resistor placed as closely to the receiver as possible. If the 100Ω differential resistor is built in to the receiver, then an externally placed resistor is not necessary. This section covers common-mode and differential voltage, and data rate.

#### 18.3.1 Common-mode and Differential Voltage

The LVDS outputs have selectable common-mode and differential voltage,  $V_{\text{OS}}$  and  $V_{\text{OD}}$ ; see [Table 11](#). See [Section 17.3.2 Output Control and Adjust](#) for more information.

Selecting the higher  $V_{\text{OS}}$  will also increase  $V_{\text{OD}}$  slightly. The differential voltage,  $V_{\text{OD}}$ , may be selected for the higher or lower value. For short LVDS lines and low noise systems, satisfactory performance may be realized with the lower  $V_{\text{OD}}$ . This will also result in lower power consumption. If the LVDS lines are long and/or the system in which the ADC12D2000RF is used is noisy, it may be necessary to select the higher  $V_{\text{OD}}$ .

#### 18.3.2 Output Data Rate

The data is produced at the output at the same rate it is sampled at the input. The minimum recommended input clock rate for this device is  $f_{\text{CLK(MIN)}}$ ; see [Table 13](#). However, it is possible to operate the device in 1:2 Demux Mode and capture data from just one 12-bit bus, e.g. just DI (or DI<sub>d</sub>) although both DI and DI<sub>d</sub> are fully operational. This will decimate the data by two and effectively halve the data rate.

#### 18.3.3 Terminating Unused LVDS Output Pins

If the ADC is used in Non-Demux Mode, then only the DI and DQ data outputs will have valid data present on them. The DI<sub>d</sub> and DQ<sub>d</sub> data outputs may be left not connected; if unused, they are internally at TRI-STATE.

Similarly, if the Q-channel is powered-down (i.e. PDQ is logic-high), the DQ data output pins, DCLKQ and ORQ may be left not connected.

## 18.4 SYNCHRONIZING MULTIPLE ADC12D2000RFS IN A SYSTEM

The AutoSync feature is not supported on the ADC12D2000RF.

The ADC12D2000RF has the DCLK Reset feature to assist the user with synchronizing multiple ADCs in a system; it is disabled by default.

If the AutoSync or DCLK Reset feature is not used, see [Table 25](#) for recommendations about terminating unused pins.

**TABLE 25. Unused AutoSync and DCLK Reset Pin Recommendation**

Pin(s)	Unused termination
RCLK+/-	Do not connect.
RCOUT1+/-	Do not connect.
RCOUT2+/-	Do not connect.
DCLK_RST+	Connect to GND via 1k $\Omega$ resistor.
DCLK_RST-	Connect to V <sub>A</sub> via 1k $\Omega$ resistor.

### 18.4.1 DCLK Reset Feature

The DCLK reset feature is available via ECM, but it is disabled by default. DCLKI and DCLKQ are always synchronized, by design, and do not require a pulse from DCLK\_RST to become synchronized.

The DCLK\_RST signal must observe certain timing requirements, which are shown in [Figure 8](#) of the Timing Diagrams. The DCLK\_RST pulse must be of a minimum width and its deassertion edge must observe setup and hold times with respect to the CLK input rising edge. These timing specifications are listed as  $t_{PWR}$ ,  $t_{SR}$  and  $t_{HR}$  and may be found in [Table 13](#).

The DCLK\_RST signal can be asserted asynchronously to the input clock. If DCLK\_RST is asserted, the DCLK output is held in a designated state (logic-high) in Demux Mode; in Non-Demux Mode, the DCLK continues to function normally. Depending upon when the DCLK\_RST signal is asserted, there may be a narrow pulse on the DCLK line during this reset event. When the DCLK\_RST signal is de-asserted, there are  $t_{SYNC\_DLY}$  CLK cycles of systematic delay and the next CLK rising edge synchronizes the DCLK output with those of other ADC12D2000RFS in the system. For 90° Mode (DDRPh = logic-high), the synchronizing edge occurs on the rising edge of CLK, 4 cycles after the first rising edge of CLK after DCLK\_RST is released. For 0° Mode (DDRPh = logic-low), this is 5 cycles instead. The DCLK output is enabled again after a constant delay of  $t_{OD}$ .

For both Demux and Non-Demux Modes, there is some uncertainty about how DCLK comes out of the reset state for the first DCLK\_RST pulse. For the second (and subsequent) DCLK\_RST pulses, the DCLK will come out of the reset state in a known way. Therefore, if using the DCLK Reset feature, it is recommended to apply one "dummy" DCLK\_RST pulse before using the second DCLK\_RST pulse to synchronize the outputs. This recommendation applies each time the device or channel is powered-on.

When using DCLK\_RST to synchronize multiple ADC12D2000RFS, it is required that the Select Phase bits in the Control Register (Addr: Eh, Bits 3,4) be the same for each ADC12D2000RF.

## 18.5 SUPPLY / GROUNDING, LAYOUT AND THERMAL RECOMMENDATIONS

### 18.5.1 Power Planes

All supply buses for the ADC should be sourced from a common linear voltage regulator. This ensures that all power buses to the ADC are turned on and off simultaneously. This single source will be split into individual sections of the power plane, with individual decoupling and connection to the different power supply buses of the ADC. Due to the low voltage but relatively high supply current requirement, the optimal solution may be to use a switching regulator to provide an intermediate low voltage, which is then regulated down to the final ADC supply voltage by a linear regulator. Please refer to the documentation provided for the ADC12D2000RFRB for additional details on specific regulators that are recommended for this configuration.

Power for the ADC should be provided through a broad plane which is located on one layer adjacent to the ground plane(s). Placing the power and ground planes on adjacent layers will provide low impedance decoupling of the ADC supplies, especially at higher frequencies. The output of a linear regulator should feed into the power plane through a low impedance multi-via connection. The power plane should be split into individual power peninsulas near the ADC. Each peninsula should feed a particular power bus on the ADC, with decoupling for that power bus connecting the peninsula to the ground plane near each power / ground pin pair. Using this technique can be difficult on many printed circuit CAD tools. To work around this, zero ohm resistors can be used to connect the power source net to the individual nets for the different ADC power buses. As a final step, the zero ohm resistors can be removed and the plane and peninsulas can be connected manually after all other error checking is completed.

### 18.5.2 Bypass Capacitors

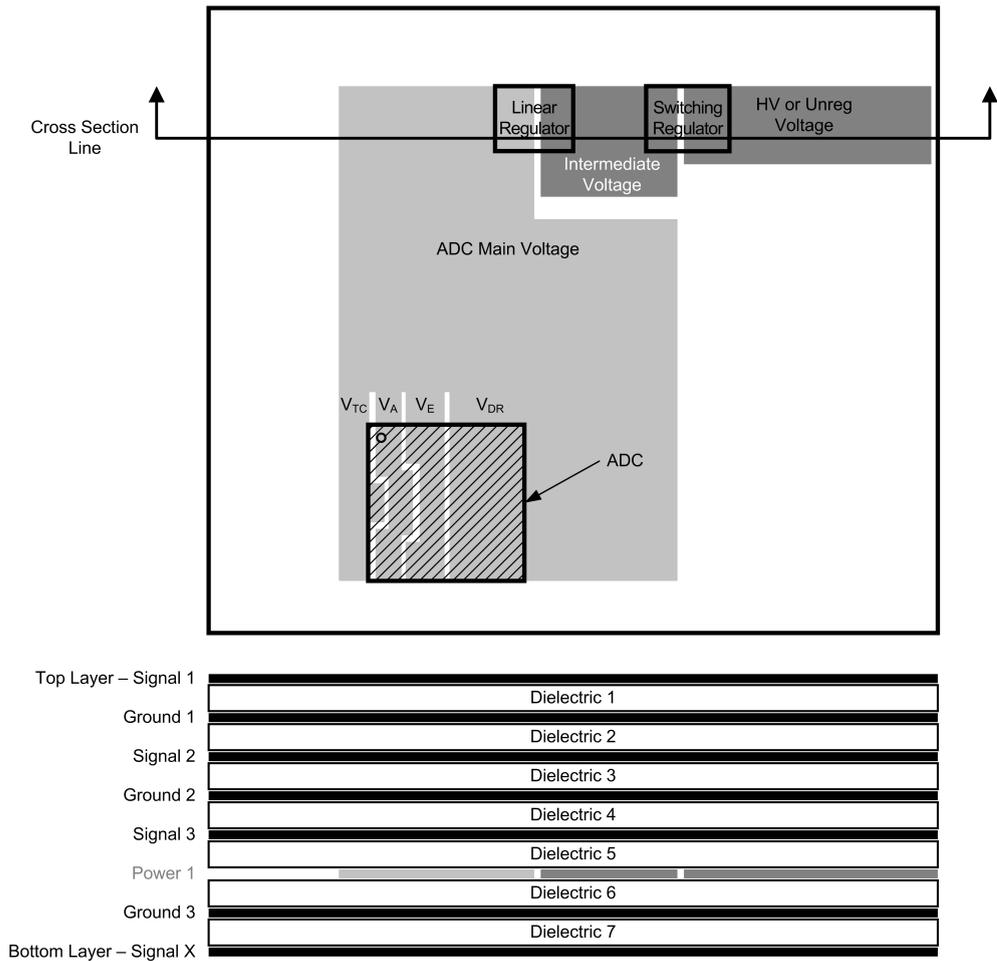

The general recommendation is to have one 100nF capacitor for each power / ground pin pair. The capacitors should be surface mount multi-layer ceramic chip capacitors similar to Panasonic part number ECJ-0EB1A104K.

### 18.5.3 Ground Planes

Grounding should be done using continuous full ground planes to minimize the impedance for all ground return paths, and provide the shortest possible image/return path for all signal traces.

### 18.5.4 Power System Example

The ADC12D2000RFRB uses continuous ground planes (except where clear areas are needed to provide appropriate impedance management for specific signals), see [Figure 19](#). Power is provided on one plane, with the ADC main supply being split into multiple zones or peninsulas for the specific power buses of the ADC. Decoupling capacitors are connected between these power bus peninsulas and the adjacent ground planes using vias. The capacitors are located as close to the individual power / ground pin pairs of the ADC as possible. In most cases, this means the capacitors are located on the opposite side of the PCB to the ADC.

30173702

FIGURE 19. Power and Grounding Example

### 18.5.5 Thermal Management

The Heat Slug Ball Grid Array (HSBGA) package is a modified version of the industry standard plastic BGA (Ball Grid Array) package. Inside the package, a copper heat spreader cap is

attached to the substrate top with exposed metal in the center top area of the package. This results in a 20% improvement (typical) in thermal performance over the standard plastic BGA package.

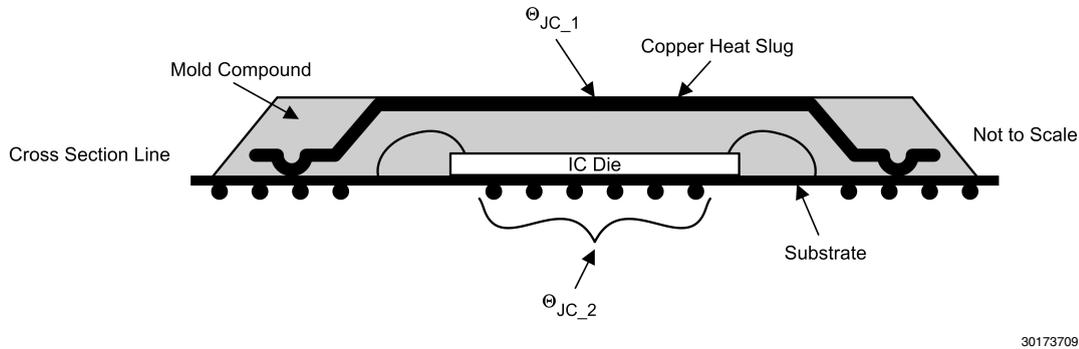

FIGURE 20. HSBGA Conceptual Drawing

The center balls are connected to the bottom of the die by vias in the package substrate, [Figure 20](#). This gives a low thermal resistance between the die and these balls. Connecting these balls to the PCB ground planes with a low thermal resistance path is the best way to dissipate the heat from the ADC. These pins should also be connected to the ground plane via a low impedance path for electrical purposes. The direct connection to the ground planes is an easy method to spread heat away from the ADC. Along with the ground plane, the parallel power planes will provide additional thermal dissipation.

The center ground balls should be soldered down to the recommended ball pads (See AN-1126). These balls will have wide traces which in turn have vias which connect to the internal ground planes, and a bottom ground pad / pour if possible. This ensures a good ground is provided for these balls, and that the optimal heat transfer will occur between these balls and the PCB ground planes.

In spite of these package enhancements, analysis using the standard JEDEC JESD51-7 four-layer PCB thermal model shows that ambient temperatures must be limited to a max of 45°C to ensure a safe operating junction temperature for the ADC12D2000RF. However, most applications using the ADC12D2000RF will have a printed circuit board which is more complex than that used in JESD51-7. Typical circuit boards will have more layers than the JESD51-7 (eight or more), several of which will be used for ground and power planes. In those applications, the thermal resistance parameters of the ADC12D2000RF and the circuit board can be used to determine the actual safe ambient operating temperature.

Three key parameters are provided to allow for modeling and calculations. Because there are two main thermal paths between the ADC die and external environment, the thermal resistance for each of these paths is provided.  $\theta_{JC1}$  represents the thermal resistance between the die and the exposed metal area on the top of the HSBGA package.  $\theta_{JC2}$  represents the thermal resistance between the die and the center group of balls on the bottom of the HSBGA package. The final parameter is the allowed maximum junction temperature, which is  $T_J$ .

In other applications, a heat sink or other thermally conductive path can be added to the top of the HSBGA package to remove heat. In those cases,  $\theta_{JC1}$  can be used along with the thermal parameters for the heat sink or other thermal coupling added. Representative heat sinks which might be used with

the ADC12D2000RF include the Cool Innovations p/n 3-1212XXG and similar products from other vendors. In many applications, the printed circuit board will provide the primary thermal path conducting heat away from the ADC package. In those cases,  $\theta_{JC2}$  can be used in conjunction with printed circuit board thermal modeling software to determine the allowed operating conditions that will maintain the die temperature below the maximum allowable limit. Additional dissipation can be achieved by coupling a heat sink to the copper pour area on the bottom side of the printed circuit board.

Typically, dissipation will occur through one predominant thermal path. In these cases, the following calculations can be used to determine the maximum safe ambient operating temperature:

$$T_J = T_A + P_D \times (\theta_{JC} + \theta_{CA})$$

$$T_J = T_A + P_{C(MAX)} \times (\theta_{JC} + \theta_{CA})$$

For  $\theta_{JC}$ , the value for the primary thermal path in the given application environment should be used ( $\theta_{JC1}$  or  $\theta_{JC2}$ ).  $\theta_{CA}$  is the thermal resistance from the case to ambient, which would typically be that of the heat sink used. Using this relationship and the desired ambient temperature, the required heat sink thermal resistance can be found. Alternately, the heat sink thermal resistance can be used to find the maximum ambient temperature. For more complex systems, thermal modeling software can be used to evaluate the printed circuit board system and determine the expected junction temperature given the total system dissipation and ambient temperature.

### 18.6 SYSTEM POWER-ON CONSIDERATIONS

There are a couple important topics to consider associated with the system power-on event including configuration and calibration, and the Data Clock.

#### 18.6.1 Power-on, Configuration, and Calibration

Following the application of power to the ADC12D2000RF, several events must take place before the output from the ADC12D2000RF is valid and at full performance; at least one full calibration must be executed with the device configured in the desired mode.

Following the application of power to the ADC12D2000RF, there is a delay of  $t_{CalDly}$  and then the Power-on Calibration is executed. This is why it is recommended to set the CalDly Pin via an external pull-up or pull-down resistor. This ensures that the state of that input will be properly set at the same time that

power is applied to the ADC and  $t_{CalDly}$  will be a known quantity. For the purpose of this section, it is assumed that CalDly is set as recommended.

The Control Bits or Pins must be set or written to configure the ADC12D2000RF in the desired mode. This must take place via either Extended Control Mode or Non-ECM (Pin Control Mode) before subsequent calibrations will yield an output at full performance in that mode. Some examples of modes include DES/Non-DES Mode, Demux/Non-demux Mode, and Full-Scale Range.

The simplest case is when device is in Non-ECM and the Control Pins are set by pull-up / down resistors, see [Figure 21](#). For this case, the settings to the Control Pins ramp concurrently to the ADC voltage. Following the delay of  $t_{CalDly}$  and the calibration execution time,  $t_{CAL}$ , the output of the ADC12D2000RF is valid and at full performance. If it takes longer than  $t_{CalDly}$  for the system to stabilize at its operating temperature, it is recommended to execute an on-command calibration at that time.

Another case is when the FPGA configures the Control Pins (Non-ECM) or writes to the SPI (ECM), see [Figure 22](#). It is

always necessary to comply with the Operating Ratings and Absolute Maximum ratings, i.e. the Control Pins may not be driven below the ground or above the supply, regardless of what the voltage currently applied to the supply is. Therefore, it is not recommended to write to the Control Pins or SPI before power is applied to the ADC12D2000RF. As long as the FPGA has completed writing to the Control Pins or SPI, the Power-on Calibration will result in a valid output at full performance. Once again, if it takes longer than  $t_{CalDly}$  for the system to stabilize at its operating temperature, it is recommended to execute an on-command calibration at that time.

Due to system requirements, it may not be possible for the FPGA to write to the Control Pins or SPI before the Power-on Calibration takes place, see [Figure 23](#). It is not critical to configure the device before the Power-on Calibration, but it is critical to realize that the output for such a case is not at its full performance. Following an On-command Calibration, the device will be at its full performance.

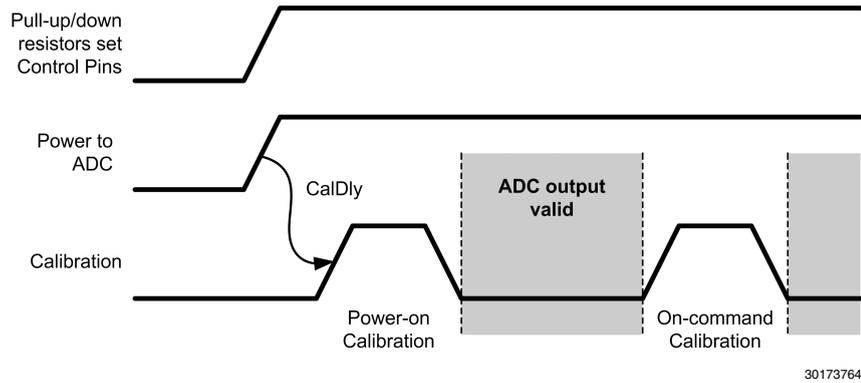

FIGURE 21. Power-on with Control Pins set by Pull-up / down Resistors

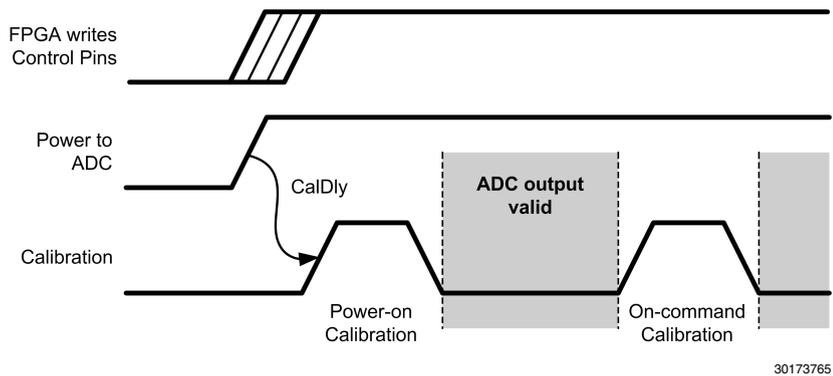

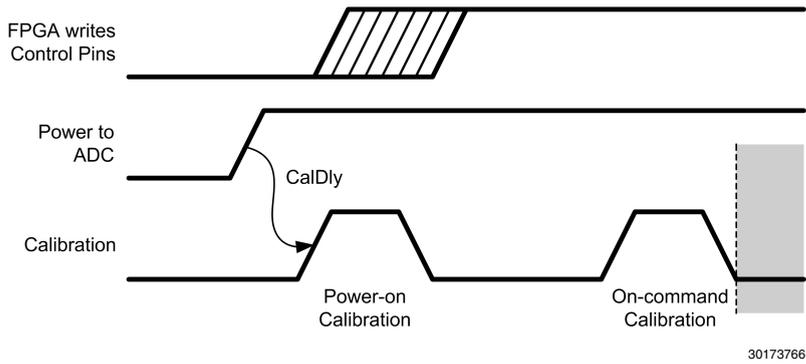

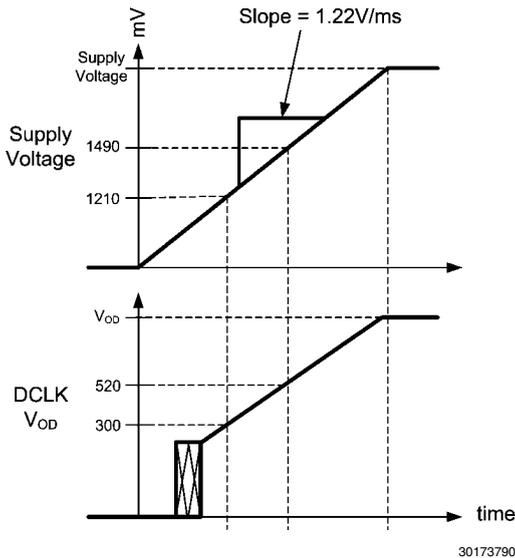

FIGURE 22. Power-on with Control Pins set by FPGA pre Power-on Cal

**FIGURE 23. Power-on with Control Pins set by FPGA post Power-on Cal**

**18.6.2 Power-on and Data Clock (DCLK)**

Many applications use the DCLK output for a system clock. For the ADC12D2000RF, each I- and Q-channel has its own DCLKI and DCLKQ, respectively. The DCLK output is always active, unless that channel is powered-down or the DCLK Reset feature is used while the device is in Demux Mode. As the supply to the ADC12D2000RF ramps, the DCLK also comes up, see this example from the ADC12D2000RFRB: [Figure 24](#). While the supply is too low, there is no output at DCLK. As the supply continues to ramp, DCLK functions intermittently with irregular frequency, but the amplitude continues to track with the supply. Much below the low end of operating supply range of the ADC12D2000RF, the DCLK is already fully operational.

**FIGURE 24. Supply and DCLK Ramping**

**18.7 RECOMMENDED SYSTEM CHIPS**

Texas Instruments recommends these other chips including temperature sensors, clocking devices, and amplifiers in order to support the ADC12D2000RF in a system design.

**18.7.1 Temperature Sensor**

The ADC12D2000RF has an on-die temperature diode connected to pins Tdiode+/- which may be used to monitor the die temperature. Texas Instruments also provides a family of temperature sensors for this application which monitor different numbers of external devices, see [Table 26](#).

**TABLE 26. Temperature Sensor Recommendation**

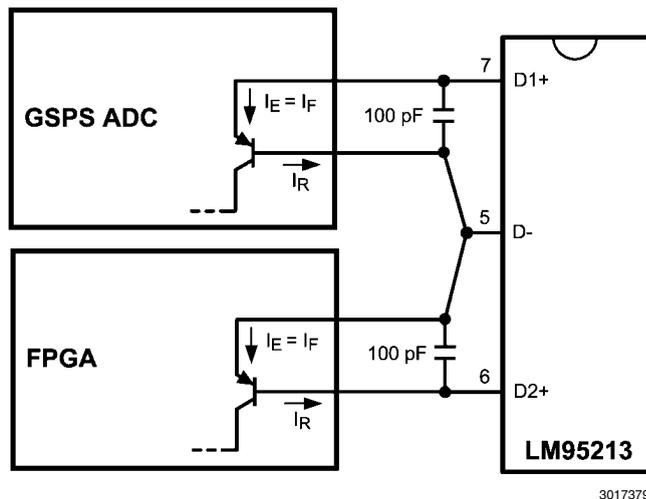

Number of External Devices Monitored	Recommended Temperature Sensor
1	LM95235
2	LM95213
4	LM95214

The temperature sensor (LM95235/13/14) is an 11-bit digital temperature sensor with a 2-wire System Management Bus (SMBus) interface that can monitor the temperature of one, two, or four remote diodes as well as its own temperature. It can be used to accurately monitor the temperature of up to one, two, or four external devices such as the ADC12D2000RF, a FPGA, other system components, and the ambient temperature.

The temperature sensor reports temperature in two different formats for +127.875°C/-128°C range and 0°/255°C range. It has a Sigma-Delta ADC core which provides the first level of noise immunity. For improved performance in a noisy environment, the temperature sensor includes programmable digital filters for Remote Diode temperature readings. When the digital filters are invoked, the resolution for the Remote Diode readings increases to 0.03125°C. For maximum flexibility and best accuracy, the temperature sensor includes offset registers that allow calibration for other types of diodes.

Diode fault detection circuitry in the temperature sensor can detect the absence or fault state of a remote diode: whether D+ is shorted to the power supply, D- or ground, or floating.

In the following typical application, the LM95213 is used to monitor the temperature of an ADC12D2000RF as well as an FPGA, see [Figure 25](#). If this feature is unused, the Tdiode+/- pins may be left floating.

30173797

FIGURE 25. Typical Temperature Sensor Application

**18.7.2 Clocking Device**

The clock source can be a PLL/VCO device such as the LMX2541SQxxxE or LMX2531LQxxxE family of products. The specific device should be selected according to the desired ADC sampling clock frequency. For example, the ADC12D2000RFRB reference board uses the LMX2541SQ2060E. Other devices which may be considered based on clock source, jitter cleaning, and distribution purposes are the LMK03XXX and LMK04XXX product families.

**18.7.3 Amplifiers for Analog Input**

The following amplifiers can be used for ADC12D2000RF applications which require DC coupled input or signal gain, neither of which can be provided with a transformer coupled input circuit:

TABLE 27. Amplifier Recommendation

Amplifier	Bandwidth	Brief features
LMH6552	1.5 GHz	Configurable gain
LMH6553	900 MHz	Output clamp and configurable gain
LMH6554	2.8 GHz	Configurable gain
LMH6555	1.2 GHz	Fixed gain

**18.7.4 Balun Recommendations for Analog Input**

The following baluns are recommended for the ADC12D2000RF for applications which require no gain. When evaluating a balun for the application of driving an ADC, some important qualities to consider are phase error and magnitude error.

TABLE 28. Balun Recommendations

Balun	Bandwidth
Mini-Circuits TC1-1-13MA+	4.5 - 3000 MHz
Anaren B0430J50100A00	400 - 3000 MHz
Mini-Circuits ADTL2-18	30 - 1800 MHz

## 19.0 Register Definitions

Twelve read / write registers provide several control and configuration options in the Extended Control Mode. These registers have no effect when the device is in the Non-extended Control Mode. Each register description below also shows the Power-On Reset (POR) state of each control bit. See [Table 29](#) for a summary. For a description of the functionality and timing to read / write the control registers, see [Section 17.2.2.1 The Serial Interface](#).

**Special Note:** Register 6h must be written to 1C0Eh for the device to perform at full rated performance for Fclk > 1.6GHz.

**TABLE 29. Register Addresses**

A3	A2	A1	A0	Hex	Register Addressed
0	0	0	0	0h	Configuration Register 1
0	0	0	1	1h	Reserved
0	0	1	0	2h	I-channel Offset
0	0	1	1	3h	I-channel Full-Scale Range
0	1	0	0	4h	Calibration Adjust

1	1	1	0	Eh	Configuration Register 2
1	1	1	1	Fh	Reserved

## Configuration Register 1

Addr: 0h (0000b)														POR state: 2000h		
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	CAL	DPS	OVS	TPM	PDI	PDQ	Res	LFS	DES	DEQ	DIQ	2SC	TSE	SDR	Res	
POR	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

- Bit 15 CAL: Calibration Enable. When this bit is set to **1b**, an on-command calibration is initiated. This bit is not reset automatically upon completion of the calibration. Therefore, the user must reset this bit to **0b** and then set it to **1b** again to execute another calibration. This bit is logically OR'd with the CAL Pin; both bit and pin must be set to **0b** before either is used to execute a calibration. ([Note 19](#))
- Bit 14 DPS: DCLK Phase Select. In DDR Mode, set this bit to **0b** to select the 0° Mode DDR Data-to-DCLK phase relationship and to **1b** to select the 90° Mode. In SDR Mode, set this bit to **0b** to transition the data on the Rising edge of DCLK; set this bit to **1b** to transition the data on the Falling edge of DCLK.
- Bit 13 OVS: Output Voltage Select. This bit sets the differential voltage level for the LVDS outputs including Data, OR, and DCLK. **0b** selects the lower level and **1b** selects the higher level. See  $V_{OD}$  in [Table 11](#) for details.
- Bit 12 TPM: Test Pattern Mode. When this bit is set to **1b**, the device will continually output a fixed digital pattern at the digital Data and OR outputs. When set to **0b**, the device will continually output the converted signal, which was present at the analog inputs. See [Section 17.3.2.6 Test Pattern Mode](#) for details about the TPM pattern.
- Bit 11 PDI: Power-down I-channel. When this bit is set to **0b**, the I-channel is fully operational; when it is set to **1b**, the I-channel is powered-down. The I-channel may be powered-down via this bit or the PDI Pin, which is active, even in ECM.
- Bit 10 PDQ: Power-down Q-channel. When this bit is set to **0b**, the Q-channel is fully operational; when it is set to **1b**, the Q-channel is powered-down. The Q-channel may be powered-down via this bit or the PDQ Pin, which is active, even in ECM.
- Bit 9 Reserved. Must be set to **0b**.
- Bit 8 LFS: Low-Frequency Select. If the sampling clock (CLK) is at or below 300 MHz, set this bit to **1b** for improved performance.
- Bit 7 DES: Dual-Edge Sampling Mode select. When this bit is set to **0b**, the device will operate in the Non-DES Mode; when it is set to **1b**, the device will operate in the DES Mode. See [Section 17.3.1.4 DES/Non-DES Mode](#) for more information.
- Bit 6 DEQ: DES Q-input select, a.k.a. DESQ Mode. When the device is in DES Mode, this bit selects the input that the device will operate on. The default setting of **0b** selects the I-input and **1b** selects the Q-input.
- Bit 5 DIQ: DES I- and Q-input, a.k.a. DESIQ Mode. When in DES Mode, setting this bit to **1b** shorts the I- and Q-inputs internally to the device. If the bit is left at its default **0b**, the I- and Q-inputs remain electrically separate. To operate the device in DESIQ Mode, Bits<7:5> must be set to **101b**. In this mode, both the I- and Q-inputs must be externally driven; see [Section 17.3.1.4 DES/Non-DES Mode](#) for more information.
- The allowed DES Modes settings are shown below: For DESCLKIQ Mode, see Addr Eh.
- | Mode          | Addr 0h, Bits<7:5> | Addr Eh, Bit<6> |
|---------------|--------------------|-----------------|
| Non-DES Mode  | <b>000b</b>        | <b>0b</b>       |
| DESI Mode     | <b>100b</b>        | <b>0b</b>       |
| DESQ Mode     | <b>110b</b>        | <b>0b</b>       |
| DESIQ Mode    | <b>101b</b>        | <b>0b</b>       |
| DESCLKIQ Mode | <b>000b</b>        | <b>1b</b>       |
- Bit 4 2SC: Two's Complement output. For the default setting of **0b**, the data is output in Offset Binary format; when set to **1b**, the data is output in Two's Complement format. ([Note 19](#))
- Bit 3 TSE: Time Stamp Enable. For the default setting of **0b**, the Time Stamp feature is not enabled; when set to **1b**, the feature is enabled. See [Section 17.3.2 Output Control and Adjust](#) for more information about this feature.
- Bit 2 SDR: Single Data Rate. For the default setting of **0b**, the data is clocked in Dual Data Rate; when set to **1b**, the data is clocked in Single Data Rate. See [Section 17.3.2 Output Control and Adjust](#) for more information about this feature. Note that for Non-Demux Mode, only 0° DDR Mode is available. See [Table 20](#) for a selection of available modes.
- Bits 1:0 Reserved. Must be set as shown.

## Reserved

Addr: 1h (0001b)														POR state: 2907h		
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	Res															
POR	0	0	1	0	1	0	0	1	0	0	0	0	0	1	1	1

Bits 15:0 Reserved. Must be set as shown.

## I-channel Offset Adjust

Addr: 2h (0010b)														POR state: 0000h		
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	Res			OS	OM(11:0)											
POR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits 15:13 Reserved. Must be set to 0b.

Bit 12 OS: Offset Sign. The default setting of 0b incurs a positive offset of a magnitude set by Bits 11:0 to the ADC output. Setting this bet to 1b incurs a negative offset of the set magnitude.

Bits 11:0 OM(11:0): Offset Magnitude. These bits determine the magnitude of the offset set at the ADC output (straight binary coding). The range is from 0 mV for OM(11:0) = 0d to 45 mV for OM(11:0) = 4095d in steps of ~11  $\mu$ V. Monotonicity is guaranteed by design only for the 9 MSBs.

Code	Offset [mV]
0000 0000 0000 (default)	0
1000 0000 0000	22.5
1111 1111 1111	45

## I-channel Full Scale Range Adjust

Addr: 3h (0011b)														POR state: 4000h		
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	Res	FM(14:0)														
POR	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit 15 Reserved. Must be set to 0b.

Bits 14:0 FM(14:0): FSR Magnitude. These bits increase the ADC full-scale range magnitude (straight binary coding.) The allowable range is from 800 mV (16384d) to 1000 mV (32767d) with the default setting at 800 mV (16384d). Monotonicity is guaranteed by design only for the 9 MSBs. A greater range of FSR values is available in ECM, i.e. FSR values above 800 mV. See  $V_{IN\_FSR}$  in [Table 8](#) for characterization details.

Code	FSR [mV]
100 0000 0000 0000 (default)	800
111 1111 1111 1111	1000

## Calibration Adjust

(Note 18)

Addr: 4h (0100b)											POR state: DB4Bh						
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Name	Res	CSS	Res						SSC	Res							
POR	1	1	0	1	1	0	1	1	0	1	0	0	1	0	1	1	

Bit 15 Reserved. Must be set as shown.

Bit 14 CSS: Calibration Sequence Select. The default **1b** selects the following calibration sequence: reset all previously calibrated elements to nominal values, do R<sub>IN</sub> Calibration, do internal linearity Calibration. Setting CSS = **0b** selects the following calibration sequence: do not reset R<sub>IN</sub> to its nominal value, skip R<sub>IN</sub> calibration, do internal linearity Calibration. The calibration must be completed at least one time with CSS = **1b** to calibrate R<sub>IN</sub>. Subsequent calibrations may be run with CSS = **0b** (skip R<sub>IN</sub> calibration) or **1b** (full R<sub>IN</sub> and internal linearity Calibration).

Bits 13:8 Reserved. Must be set as shown.

Bit 7 SSC: SPI Scan Control. Setting this control bit to **1b** allows the calibration values, stored in Addr: 5h, to be read / written. When not reading / writing the calibration values, this control bit should left at its default **0b** setting. See [Section 17.3.3 Calibration Feature](#) for more information.

Bits 6:0 Reserved. Must be set as shown.

## Calibration Values

(Note 18)

Addr: 5h (0101b)											POR state: XXXXh					
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	SS(15:0)															
POR	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X

Bits 15:0 SS(15:0): SPI Scan. When the ADC performs a self-calibration, the values for the calibration are stored in this register and may be read from/ written to it. Set SSC (Addr: 4h, Bit 7) to read / write. See [Section 17.3.3 Calibration Feature](#) for more information.

## Bias Adjust

Addr: 6h (0110b)											POR state: 1C2Eh					
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	MPA(15:0)															
POR	0	0	0	1	1	1	0	0	0	0	1	0	1	1	1	0

Bits 15:0 MPA(15:0): Max Power Adjust. **This register must be written to 1C0Eh to achieve full rated performance for Fclk > 1.6GHz.**

## DES Timing Adjust

Addr: 7h (0111b)											POR state: 8142h					
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	DTA(6:0)							Res								
POR	1	0	0	0	0	0	0	1	0	1	0	0	0	0	1	0

Bits 15:9 DTA(6:0): DES Mode Timing Adjust. In the DES Mode, the time at which the falling edge sampling clock samples relative to the rising edge of the sampling clock may be adjusted; the automatic duty cycle correction continues to function. See [Section 17.3.1 Input Control and Adjust](#) for more information. The nominal step size is 30fs.

Bits 8:0 Reserved. Must be set as shown.

## Reserved

Addr: 8h (1000b)														POR state: 0F0Fh

Name	Res	FM(14:0)														
POR	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit 15 Reserved. Must be set to 0b.

Bits 14:0 FM(14:0): FSR Magnitude. These bits increase the ADC full-scale range magnitude (straight binary coding.) The allowable range is from 800 mV (16384d) to 1000 mV (32767d) with the default setting at 800 mV (16384d). Monotonicity is guaranteed by design only for the 9 MSBs. A greater range of FSR values is available in ECM, i.e. FSR values above 800 mV. See  $V_{IN\_FSR}$  in [Table 8](#) for characterization details.

Code	FSR [mV]
100 0000 0000 0000 (default)	800
111 1111 1111 1111	1000

## Aperture Delay Coarse Adjust

Addr: Ch (1100b)													POR state: 0004h			
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	CAM(11:0)											STA	DCC	Res		
POR	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Using the  $t_{AD}$  Adjust feature at its maximum setting, for the maximum sampling clock rate, may affect the integrity of the sampling clock on chip. Therefore, it is not recommended to do so. The maximum setting for the coarse adjust is 825ps. The period for the maximum sampling clock rate is 500ps, so it should not be necessary to exceed this value in any case.

- Bits 15:4 CAM(11:0): Coarse Adjust Magnitude. This 12-bit value determines the amount of delay that will be applied to the input CLK signal. The range is 0 ps delay for CAM(11:0) = 0d to a maximum delay of 825 ps for CAM(11:0) = 2431d ( $\pm 95$  ps due to PVT variation) in steps of  $\sim 340$  fs. For code CAM(11:0) = 2432d and above, the delay saturates and the maximum delay applies. Additional, finer delay steps are available in register Dh. Either STA (Bit 3) or SA (Addr: Dh, Bit 8) must be selected to enable this function.
- Bit 3 STA: Select  $t_{AD}$  Adjust. Set this bit to 1b to enable the  $t_{AD}$  adjust feature, which will make both coarse and fine adjustment settings, i.e. CAM(11:0) and FAM(5:0), available.
- Bit 2 DCC: Duty Cycle Correct. This bit can be set to 0b to disable the automatic duty-cycle stabilizer feature of the chip. This feature is enabled by default.
- Bits 1:0 Reserved. Must be set to 0b.

## Aperture Delay Fine Adjust

(Note 18)

Addr: Dh (1101b)													POR state: 0000h			
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	FAM(5:0)						Res	SA	Res							
POR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Using the  $t_{AD}$  Adjust feature at its maximum setting, for the maximum sampling clock rate, may affect the integrity of the sampling clock on chip. Therefore, it is not recommended to do so. The maximum setting for the coarse adjust is 825ps. The period for the maximum sampling clock rate is 500ps, so it should not be necessary to exceed this value in any case.

- Bits 15:10 FAM(5:0): Fine Aperture Adjust Magnitude. This 6-bit value determines the amount of additional delay that will be applied to the input CLK when the Clock Phase Adjust feature is enabled via STA (Addr: Ch, Bit 3) or SA (Addr: Dh, Bit 8). The range is straight binary from 0 ps delay for FAM(5:0) = 0d to 2.3 ps delay for FAM(5:0) = 63d ( $\pm 300$  fs due to PVT variation) in steps of  $\sim 36$  fs.
- Bit 9 Reserved. Must be set to 0b.
- Bit 8 SA: Select  $t_{AD}$  Adjust. Set this bit to 1b to enable the  $t_{AD}$  adjust feature. This bit is the same as STA (Addr: Ch, Bit 3), except that if SA is enabled, then the value of the STA bit is ignored.
- Bits 7:0 Reserved. Must be set as shown.

## Configuration Register 2

Addr: Eh (1110b)													POR state: 0003h			
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Name	Res									DCK	Res					DR
POR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

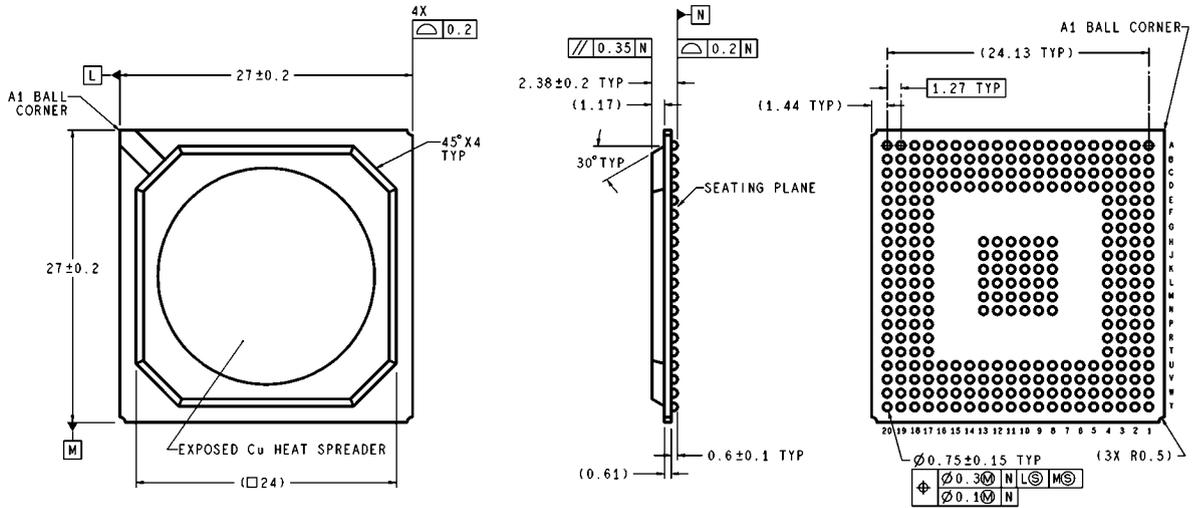

- Bits 15:7 Reserved. Must be set as shown.
- Bit 6 DCK: DESCLKIQ Mode. Set this bit to 1b to enable Dual-Edge Sampling, in which the Sampling Clock samples the I- and Q-channels 180° out of phase with respect to one another, i.e. the DESCLKIQ Mode. To select the DESCLKIQ Mode, Addr: 0h, Bits<7:5> must also be set to 000b. See [Section 17.3.1.4 DES/Non-DES Mode](#) for more information.
- Bits 5:1 Reserved. Must be set as shown.
- Bit 0 DR: Disable Reset. The default setting of 1b leaves the DCLK\_RST functionality disabled. Set this bit to 0b to enable DCLK\_RST functionality.

## Reserved

Addr: Fh (1111b)													POR state: 001Eh
